M. Huchard does not admit that either morbus cordis or angina pectoris is a contra-indication to the administration of chloroform. He maintains that all patients suffering from morbus cordis, whether mitral or aortic, can be anæsthetised. The only contra-indication, according to him, is when the patient is suffering from toxic alimentary dyspnœa or from a very weak systolic action of the heart. In the latter case anæsthesia is possible, but in the former case the patient should be fed on milk diet so as to get rid of the toxæmia before anæsthesia is undertaken. M. Huchard lays great stress upon the point that anæsthesia should be absolutely complete especially in the case of patients suffering from morbus cordis. In these latter cases the principal danger lies in incomplete anæsthesia so that all reflex action is not completely abolished, and reflex actions are the principal causes of the sometimes fatal syncope which occurs under anæsthesia.

### *Hygiene in the Army.*

On the recent occasion of young soldiers joining the colours the military governor of Paris directed the adoption of the following measures with a view to the limitation of venereal diseases in the army :—1. One of the hygienic conferences held by regimental surgeons for the information of officers and non-commissioned officers shall be devoted to an explanation of the dangers of venereal diseases and the manner of dealing with them. 2. The monthly medical inspection ordered by Article 71 (infantry) of the service regulations shall be of a personal nature as far as possible, each man being examined separately. 3. Measures shall be taken to ensure that non-commissioned officers may be able to consult the regimental surgeons without the fact coming to the knowledge of their subordinates. 4. The supervision of special patients shall be guaranteed by means of a special register or cards for each person kept by the medical officer himself and stored in the poison cupboard of which he alone has the key. Men suffering from the diseases in question shall also be examined periodically so that they may be certified as being still under treatment. 5. Punishment shall not, as a rule, be inflicted in connexion with venereal diseases except in flagrant cases of concealment. This last regulation has already been adopted throughout the greater part of the service ; in general only those soldiers are punished who refuse to give information as to the place where they contracted their disorder and who thereby impede the authorities in the taking of measures to protect their comrades. It would be a good thing if this last condition were maintained. Attention is also just now being given to the question of tuberculosis in the army. M. Lachaud has submitted to the Chamber of Deputies two reports recommending that the *conseils de revision* should be empowered (1) to reject young men suspected of a tendency to become tuberculous and (2) to establish sanatoriums for soldiers who have become tuberculous during their period of service. This last condition would have the effect of modifying the law relating to discharge with certificate No. 2 for soldiers thus attacked. These recommendations were submitted to the Chamber on Dec 19th, 1901, at the instance of the Commission of Public Hygiene, with the result that the Chamber has recognised their urgency and has remitted them to the Army Commission.

Jan. 14th.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

### *Death of Dr. Lesslie M. Sweetnam.*

TORONTO lost one of her foremost and most distinguished surgeons when Dr. L. M. Sweetnam died at Johns Hopkins Hospital, Baltimore, Maryland, U.S.A., on Dec. 11th. Two or three weeks before his death Dr. Sweetnam was operating on a young man with a gangrenous arm the result of a gunshot wound and had the misfortune to cut one of his fingers during the operation. The patient subsequently died from malignant œdema. Dr. Sweetnam contracted blood-poisoning, but for a week or 10 days he continued at his work. Then he went to Baltimore for rest and recuperation. He was recovering from the septicæmia when convulsions suddenly occurred which terminated fatally. Dr. Sweetnam was only 42 years of age, but had already reached the top of his chosen profession. He graduated in 1881 from Toronto and Victoria Universities and at the time of his demise was Associate Professor of Surgery in Toronto University and surgeon to St. Michael's Hospital and to the General Hospital, Toronto.

### *Canadian Field Hospital for South Africa.*

It seems to be very gratifying to the medical profession, particularly to military surgeons, that the offer of a Canadian field hospital for service in South Africa has been accepted by the Imperial Government. It will be a distinct unit and will have no connexion with the Canadian Mounted Rifles which will shortly leave Halifax, Nova Scotia, for the seat of war. Dr. A. N. Worthington of Sherbrooke, Quebec, will be in charge as surgeon-colonel, that officer having already seen service in the South African campaign, and he will have associated with him Dr. Carleton Jones of Halifax as surgeon-major ; Dr. H. D. Johnson, Charlotte Town, Prince Edward Island, as surgeon-captain ; and Dr. Roberts and Dr. H. E. Tremayne as surgeon-lieutenants, the last two being young practitioners of Toronto.

### *Canadian Medical Protective Association.*

The prospectus of this recently formed association has just been issued to the medical profession in the Dominion. Two years ago, when the Canadian Medical Association met in Ottawa, a strong committee was appointed to report on the formation of such association at the next annual meeting. This was done at the last annual meeting held at Winnipeg, with the result that the organisation was at once perfected and the officers were appointed for the first year. These at once got to work and it is understood that already many members have been secured. The annual fee is $2 50, and the object of the association is the protection of its members from suits at law for alleged malpractice. A meeting of the association will be held annually at the same time and place as the annual meeting of the Canadian Medical Association. A marked feature of the constitution appears in the sentence : "In no case shall the association compromise." The new organisation has absorbed the Medical Defence Union which existed in the eastern townships of the province of Quebec in connexion with the St. Francis District Medical Association. The president is Dr. R. W. Powell, Ottawa, a past-president of the Canadian Medical Association, and the secretary is Dr. F. W. McKinnon, Ottawa.

### *Dean of McGill Medical Faculty.*

After serving for many years as dean of the medical faculty of McGill University Dr. Craik has resigned, and Dr. Thomas G. Roddick, M.P., selected unanimously by his fellow members of the faculty, has been appointed successor by the governors of the University. Dr. Craik has been honoured by being appointed a member of the Board of Governors, the second instance in the history of this famous University where such a distinction has been conferred on a member of a teaching faculty. The new dean has had a distinguished career in the Canadian medical profession. Born at Harbour Grace, Newfoundland, in 1846, he entered McGill University and graduated M.D. as Holmes Gold Medalist in 1868. His connexion with the medical faculty of McGill University began in 1872 and he at present holds the chair of surgery in that institution. He is a past-president of the Montreal Medico-Chirurgical Society, of the Canadian Medical Association, and of the British Medical Association, being the first colonial to be the recipient of the last-named honour. In 1896 he was first elected to the Canadian House of Commons, and ever since he has been prominently identified with bringing about inter-provincial registration between the various provinces of the Dominion. It is fully expected that Dr. Roddick's Bill in this connexion will receive Parliamentary sanction at the coming session of the Dominion House.

### *Vaccination in Quebec.*

The Board of Health of the Province of Quebec, owing to the extensive outbreak of small-pox which has existed now of hospitals while a member of the English Local Government Board.

### *Chair of Physiology, Trinity College, Dublin.*

At a special meeting of the President and Fellows of the Royal College of Physicians of Ireland held on Jan. 10th Dr. William H. Thompson, Dunville Professor of Physiology, Queen's College, Belfast, was elected to the chair of Institutes of Medicine in the School of Physic, Trinity College, Dublin, rendered vacant by the resignation of Professor J. M. Purser.

### *Ulster Medical Society.*

The third meeting of the Ulster Medical Society for this session was held in the Belfast Museum on Jan. 10th, Professor W. Whitla, the President, being in the chair. A report having been received from the council in reference to the new medical institute, it was moved by Dr. P. Redfern and seconded by Mr. F. E. MacFarland to accept the very generous offer of the President to build and to equip a medical institute for the society. It was also decided, on the motion of Dr. A. Dempsey, seconded by Professor J. A. Lindsay, to accept the site offered by the President—that is, a plot of ground having a frontage of 50 feet along College-square North, by 93 feet in depth, at a fee farm rent of £60 annually, said rent to begin on May 1st, 1902, and possession to be given at once. Dr. W. Calwell showed (1) a case of Paralysis of the Hypoglossal Nerve, and (2) a case of peculiar Congenital Acro-Dystrophy-Hyperkeratosis, Recurrent Bullæ, &c. Dr. John McCaw showed a case of Birth Palsy of the Hemiplegic Type. Dr. A. B. Mitchell read notes of (1) a case in which six feet of the Small Intestine were successfully Resected; and (2) a case of Intussusception in which Laparotomy was performed. An interesting discussion followed the reading of these communications.

### *Kissing the Book.*

His Honour County Court Judge Kisbey at the Lurgan Quarter Sessions on Jan. 9th made some most sensible remarks on the methods of swearing witnesses. As a plaintiff was about to go through this process his Honour remarked that he wished to impress upon those who found it necessary to attend that court and give evidence that it was not absolutely necessary for them to kiss the book, it being perfectly legal and equally as binding on them to be sworn with uplifted hand, and the same punishment could in that case be inflicted if a witness were found to be perjuring himself. He referred to this matter because of the controversy that had recently taken place in England in regard to it. There the judges, acting, as he thought, with the greatest propriety, had been telling witnesses that they were just as entitled to take the oath with uplifted hand as by kissing the book. No doubt the latter method had great antiquity to justify it, but seeing that the book was kissed by persons in various stations in life, some of whom might be suffering from some disease, he thought the uplifting of one hand the safest method. For instance, it would be very dangerous, he pointed out, for a healthy person to kiss a book that had been similarly used just previously by a consumptive. Of course, if people wished to kiss the book they could do so, but he only desired to inform them that the taking of the oath by uplifting the hand was equally as good. Nothing could be more sensible or more in accordance with sound sanitary views than these most apt remarks of Judge Kisbey.

### *The Water-supply of Port Ballintrae.*

Owing to the lamented death of Mr. James Traill, son of Dr. Anthony Traill of Trinity College, which took place after residing at the favourite watering-place of Port Ballintrae, situated in North Antrim, near Portrush, on Nov. 11th, a great deal of discussion has arisen as to the drainage and water-supply of the district. Mr. D. Huey, the medical officer of Bushmills Dispensary District, has, in a report, urged on the Ballymoney Rural Council the importance of employing an expert to examine the proposed new water-supply (the present is from wells liable to pollution). An architect has been appointed to prepare plans and specifications for the new water-supply.

### *Queen's College, Belfast.*

On Jan. 7th a dinner in honour of Professor Purser, M.A., LL.D., D.Sc., was given in the great hall of Queen's College, Belfast, on the occasion of his retirement from the professorship of mathematics, a position which he has occupied with such marked distinction for a lengthened period of 38 years—that is, more than two-thirds of the whole life of the college. The President of the college occupied the chair and after the usual loyal toasts Dr. Joseph Larmor, Fellow of St. John's College, Cambridge, and secretary of the Royal Society, a Belfast man who was a former distinguished pupil of Professor Purser, proposed, in very happy terms, the toast of the evening, "The Health of Professor Purser," to which that gentleman very feelingly replied. The meeting was a most successful one, many of Professor Purser's old students, arts and medical, coming long distances to do their old teacher honour on his retirement.

### *The Forster Green Hospital for Consumption.*

At the annual meeting of the supporters of this hospital, held on Jan. 13th, it was reported that during the past year, beginning with 23 patients there had been in addition 142, or a total of 165, dealt with. In the out-patient department there had been 1655 attendances, 474 of which were those of new patients. Though the number of deaths from consumption in England and Scotland had decreased during the last 10 years, in Ireland there had been an increase, and in the whole of Ireland there was for the working classes an accommodation of only 85 beds, of which a large number were not free. Financially there was only a deficit of £254 1*s.* 3*d.* The public had given £26 in contributions more than last year, but the increased cost of keeping the extra number of patients amouted to between £600 and £700 The Earl of Shaftesbury sent a donation of £50 for the hospital.

### *The Belfast Asylum.*

The city corporation of Belfast, which took away 60 acres (of which one half is arable, the remainder being wood and stream) of the grounds of the Purdysburn Asylum, for an infectious diseases hospital, has now decided to acquire a farm of 88½ acres adjoining the asylum grounds at £80 per statute acre. When this is added to the asylum grounds it will give a total of about 166 acres.

Jan. 14th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Death of Dr. Le Baron.*

DR. LE BARON, founder and honorary president of the Society of Medical Practitioners of the Seine, and the delegate of the various medical syndicates to the Conseil Supérieur de la Mutualité, died on Jan. 2nd. He was born at Segré in 1855, and studied medicine at Paris. On April 2nd, 1891, he gathered together sundry of his professional brethren and founded the Syndicate of Medical Practitioners of the Seine, and ever since that date he has worked for the benefit of this association with unbounded patience and energy. He gave all his time to this work and for some time held the office of vice-president of the Association of Medical Syndicates in France. He was the first and only person who dared at the congress of friendly societies which was held at Bordeaux in 1892 to raise the question of the medical side of friendly societies and to reproach the members with the shameless way in which medical men's services were exploited by a certain number of friendly societies. Dr. Le Baron was an archæologist of no small merit, and in his capacity as a member of the Society for the Preservation of Parisian Monuments he succeeded in preserving from destruction the ruins of the old school of medicine in the Rue de la Boucherie. His death will be a great source of regret to his numerous friends

### *Resignation of Professor Lannelongue as President of the General Association of French Medicine.*

Professor Lannelongue has just sent in his resignation as President of the above association. The resignation dates from the discussion recently held as to the admission of women to the association—that is to say, not merely the admission of women medical practitioners, but also of the wives of medical men. Professor Lannelongue had no hesitation in voting with the younger members of the association in the cause of progress. Pressing inquiries have been made of Dr. Brouardel as to whether he would accept the office in succession to his colleague.

### *Examination Frauds*

With a view to doing away with fraudulent practices in examinations the following laws have been passed:—

1. Every fraud committed in connexion with public examinations by the passing of which the candidate enters the public service or acquires a State diploma shall constitute an offence (*délit*).

have been considerably enlarged. Seating accommodation has been provided for out-patients who formerly used to wait about in the street outside the hospital. It is contemplated to enlarged the wards for children and to erect a new casualty room—A meeting of the dental profession was recently held in Sydney to adopt a constitution for a Dental Hospital. The constitution, with a few alterations, was adopted. It provides for gratuitous advice and treatment in all diseases of the mouth to such poor and necessitous persons as are unable to procure the same at their own expense, and that honorary physicians and surgeons shall be appointed to render assistance in administering anæsthetics and in such operations as are not within the scope of ordinary dental surgery.—The Mayoress of Sydney recently opened a new wing of the Infants' Home at Ashfield. At present the home accommodates 20 women and 50 children; in future it will take in 64 children, and comfortable quarters for nurses are provided.

### *Appointments, &c.*

The following have been appointed Examiners at the Sydney University for the Faculty of Medicine:—Anatomy, Dr. A. E Mills; physiology, Professor E. C. Stirling; pathology, Dr. G. E. Rennie; materia medica, Dr. A. Watson Munro; medicine, the Hon. Dr. Mackellar; surgery, Mr. G. T. Hankins; midwifery, Dr. S. H. MacCulloch; gynæcology, Dr. Fourness Barrington; clinical medicine, Dr. P. Sydney Jones; clinical surgery, Dr. T. Fiaschi; psychological medicine, Dr. Eric Sinclair; ophthalmic medicine and surgery, Dr. W. Adillo Maher; medical jurisprudence and public health, Dr. W. G. Armstrong.—A "Government Gazette" announces the regrading of the Government medical officers, whose classification, without change in regard to salary, will in future be as follows: Dr. R T. Paton, Government medical officer and vaccinator for Sydney and visiting surgeon, Darlinghurst Gaol; Mr. G. H. Taylor, second Government medical officer and vaccinator for Sydney, pathologist and assisting visiting surgeon, Darlinghurst Gaol.

### *Obituary*

Mr. Clifton Sturt of Bulli (New South Wales) died suddenly from aneurysm while away on a holiday trip in New Zealand. He was away for his health. It may not be generally known that Dr. James Foulis, who died recently in Edinburgh, was a Sydney boy, the son of the late Dr. John Foulis who had a large practice in Sydney. In his younger days Dr. James Foulis was a noted cricketer and played as wicket-keeper for the New South Wales eleven. He took his B A. degree at the Sydney University. He was the first white boy born in Lord Howe Island.

Dec. 10th, 1901.

## Medical News.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—On Jan. 8th the quarterly court of the directors of this society was held, Mr. Christopher Heath, the President, being in the chair. Two new members were elected and the deaths of four members were reported, as well as that of Mr. J. R. Upton, an honorary member who for many years had kindly given his services as solicitor to the society. The election of a member was declared void. A fresh application for grants was made by a widow, aged 74 years, and relief at the rate of £30 per annum was given. It was resolved to distribute £1282 among the 52 widows, 13 orphans, and the four recipients from the Copeland Fund, now receiving half-yearly grants. The Christmas present, £569, had been given on Dec. 18th, 1901. The expenses of the quarter were £77 7*s.* 6*d.*

THRIFT AND SOCIAL REFORM.—At a council meeting of the National Thrift Society held on Jan. 11th the report for last year was approved and adopted. The report stated that the society's operations had been vigorously carried on in various parts of Great Britain and Ireland, whilst a special feature of the year's work had been the establishment of a Social Reform Branch which had in hand the petition to the authorities respecting the abatement of unnecessary street noises throughout the metropolis. It was proposed to continue this branch of the work under the name of the "Betterment of London Association."

NEW COTTAGE HOSPITAL AT SUTTON, SURREY.—At Sutton, on Jan. 7th, a cottage hospital, the gift of Mr. Passmore Edwards, was opened to the public. The hospital will provide accommodation for 12 patients and advantage has been taken of modern improvements in hospital building and furnishing. The hospital has cost £3000.

HOSPITAL FOR SICK CHILDREN.—It is announced that a bazaar in aid of the Hospital for Sick Children, Great Ormond-street, will be held about the time of the Coronation under the immediate patronage of Her Majesty the Queen, the Prince and Princess of Wales, Princess Louise Duchess of Fife and the Duke of Fife, and Prince and Princess Charles of Denmark.

THE Chelsea Hospital for Women has received from "H. M. E" another sum of £500. This and the preceding similar contribution from the same benefactress have been placed on deposit as a guarantee fund against emergency. The hospital already owes the greater part of its recent improvement to "H. M. E."

LUNACY IN DORSETSHIRE.—At a special meeting of the County Council of Dorset held at the Shire Hall, Dorchester, on Jan. 8th, the Visiting Committee, through its chairman, Lord Digby, submitted a proposal for additional buildings at an estimated cost of about £40,000. The proposal of the Visiting Committee, which is to build a detached house for 100 private patients, was unanimously approved, and the plans, which have been prepared by the architect of the council, Mr. G. T. Hine, gave complete satisfaction to the members. As Dorsetshire was the first county in England to take advantage of Section 255 of the Lunacy Act, 1890, by providing accommodation for private patients in connexion with the county institution this new and further development of the private side of the institution will be watched and followed by many keen and critical eyes.

DINNER TO DR. WILLIAM CAYLEY.—At the Prince's Restaurant, Piccadilly, on Jan. 9th, a most successful dinner was given to Dr. William Cayley by a large number of his former house physicians and clinical clerks, on the occasion of his retirement from the post of senior physician to the Middlesex Hospital, with which institution he had been actively connected for 35 years. The toast of "The Guest of the Evening" was very eloquently proposed by the chairman, Mr. E. A. Fardon, who, after some apposite remarks from Mr. J. Bland-Sutton, presented Dr. Cayley, on behalf of those present, as well as of many who were prevented from attending, with a loving cup suitably inscribed. On Dr. Cayley rising to reply the enthusiasm was unbounded, and it was some minutes before he could obtain a hearing. At the conclusion of his speech the loving-cup was filled and passed round.

FREEMASONRY.—*The Rahere Lodge, No. 2546.*—An ordinary meeting of the Rahere Lodge was held at Frascati's Restaurant, Oxford-street, W., on Jan. 14th, Bro. P. S. Abraham, M.D. Dub., W.M., in the chair. Bros. Scott and Edge were admitted to the third degree, Bro. Walton Read was admitted to the second degree, and Messrs. Sydney L. Harke, W. Perceval Yetts, and J. C. Stoyte Dunn were initiated into Freemasonry. A sum of 10 guineas was voted from the lodge funds to each of the masonic charities. A past grand officer's jewel was given to W. Bro. the Rev. Sir Borrodaile Savory, Bart., Grand Chaplain. The lodge also contributed the sum of 10 guineas towards a gift to W. Bro. Clement Godson, M.D. Aberd., Treasurer, on the occasion of his silver wedding.—*University of London Lodge, No. 2033.*—The members of the University of London Lodge held their first meeting in 1902 at Freemasons' Tavern on Thursday, January 9th, under the presidency of Dr. Samuel Hague, Mr. W. R. McConnell, K C., and Dr. A. E. Sansom supporting the chair. After the masonic ceremonies were completed about 25 of the brethren dined together. This Lodge is now nearly 20 years old and numbers amongst its past masters the late Alderman Fowler, Lord Mayor; the late Lord Herschell, Lord Chancellor; the late Dr. Alfred Meadows; and his honour Judge Philbrick, K.C. The secretary is Mr. W. J. Spratling, any letters addressed to whom at Freemasons' Tavern will receive prompt attention This Lodge is in close touch with the sister University Lodges, the "Isaac Newton," Cambridge, the "Apollo," Oxford, and the "University," Durham.

in that province for some months, has recently issued a special order to all municipalities to enact legislation according to the Quebec Public Health Act and to see that such by-laws are adopted and strictly carried out with regard to vaccination. Such by-laws being in force, any person who cannot establish that he has been successfully vaccinated within seven years or unsuccessfully within six months, unless he has had small-pox or unless his health does not permit of his being vaccinated, will be liable to a fine of five dollars, with another dollar for each day of delay. In the province of Ontario small-pox continues to increase and the Ontario Board of Health has repeatedly called attention to the provisions of the Ontario Health Act. Owing to the mildness of the outbreak people are shunning and neglecting vaccination

### *Annual Medical Report of Muskoka Sanatorium for Phthisis.*

Dr. J. H. Elliott, the medical superintendent of this institution, has handed out the last annual report. The last official year ended with 61 patients in residence, although there is only accommodation for 50 patients. The increased numbers have been accommodated by the means of tents on the lawns. During the past year 99 male patients were treated; 15 were discharged apparently cured and 29 with the disease arrested. Of the 29, 14 gave promise of cure had they remained longer in the hospital. This would mean that 29 out of 99, or nearly 30 per cent., could have been apparently cured had a longer stay been possible. It is considered highly satisfactory that in 44 out of 99 patients the disease has undergone more or less complete subsidence. These 99 cases were classified on admission as follows: incipient, 24; advanced, 43; and far advanced, 32. The average gain in weight had been 13 pounds. Of the female patients 59 were admitted during the year, 87 being treated altogether. Thus the total number treated during the year amounts to 186

Toronto, Jan. 3rd.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

### *The Bubonic Plague.*

A FRESH case of plague has developed in Sydney, in a man working in a produce store, but it appears to be a sporadic case, no others having occurred. The patient is progressing favourably. Rat-catching is being vigorously prosecuted, the wharves are being cleaned, and house inspection is being carried on. In the other States no special precautions have been taken as to quarantine, but vessels from Sydney are subjected to fumigation at Brisbane and rat-catching is continued in all the States. Masters of vessels leaving Sydney for other ports in the Commonwealth must be furnished with a certificate that their vessels have been properly fumigated before leaving.

### *Health of Sydney.*

The quarterly report of the officer of health for the metropolitan combined districts of Sydney (Dr. W. G. Armstrong), just published, stated that the number of deaths registered in the metropolis during the quarter ending Sept. 30th was greater than that of any consecutive three months since the year 1898 The principal factor in this increase in the deaths was pneumonia, which caused far more deaths than any other single disease Other respiratory diseases—bronchitis, whooping-cough, and influenza—were also very fatal, accounting for 24 per cent. of all deaths. Phthisis caused 145 deaths, or 14 more than the average for the same quarter during the past five years 16 deaths occurred from cerebro-spinal fever, which has been more or less epidemic in Sydney since the latter part of 1899, and appears to be increasing The number of cases of infectious disease notified during the quarter showed a considerable increase over the figures for preceding years. Scarlet fever appears to have been steadily increasing in prevalence during the whole of the year. Typhoid fever showed the usual winter fall, but was more prevalent than last year. Whooping-cough had been more fatal than for some years past.

### *The Friendly Societies of New South Wales.*

The Friendly Societies Act (1899) of New South Wales provided that within two years all friendly societies must be registered, and this registration involved that the tables of contributions payable by members should be certified to by a qualified actuary. The societies, however, do not want to register and to reveal their financial position, which with very few exceptions is thoroughly unsound According to a valuation made by the Government Actuary of Friendly Societies, the liabilities incurred by the societies on sickness and funeral benefits amounted to £3,795,013, while the funds in hand were only £537,710, and the present value of future contributions was only £2,003,472, leaving an absolute deficiency of £1,253,831, equal to 6*s.* 8*d* in the £ In Victoria the accumulated funds are double those in New South Wales and the rates are higher, and in New Zealand, with only half the number of members the funds per head are double those in New South Wales. Hence the societies in New South Wales are agitating for a repeal of the Act of 1899.

### *Prevention of Tuberculosis.*

A largely attended public meeting was held in Melbourne on Dec. 2nd, 1901, to form a Victorian Association for the Prevention of Consumption and other Forms of Tuberculosis on the lines of the National Association in Great Britain. His Excellency the Governor-General presided and made an excellent speech, remarking that while stringent laws and regulations, which have been successful in their effect, have been made to prevent the spread of hydrophobia, small-pox, fevers, and other contagious diseases the prevention of the spread of consumption had not been hitherto seriously undertaken. Nevertheless, more people were killed by it than by any other disease, and in Melbourne alone 800 people died from consumption every year, people mostly in the prime of life. But he had come to the meeting to learn, not to teach. Experts held different views on some questions connected with tuberculosis, but he believed that he was on safe, though unsavoury, ground in saying that one of the most fruitful sources of the spread of consumption was the abominable habit of promiscuous expectoration. He also thought that the inordinate length to which ladies' skirts were worn was a danger in connexion with the spread of consumption and he humbly appealed to the ladies to curtail their skirts and to leave the cleansing of the streets to the municipal authorities The proposition for the formation of an association to prevent tuberculosis was moved by the Prime Minister of the Commonwealth, who said that places should be provided for the worst cases to be treated and also for those who were less seriously affected. This meant money, and it remained to be seen whether in this first year of their nationhood they were willing to find the money to provide against a danger that was greater than war and more destructive than any war in which the Empire might be engaged Dr. D. A. Gresswell (chairman of the Public Board of Health), the mayor of Melbourne, Dr. Jamieson (the city health officer), Sir Thomas N. FitzGerald, and others addressed the meeting, and the association was formed and a standing committee was appointed to give effect to its objects.

### *Hospital Affairs*

In the New South Wales Legislative Assembly the following motion by the Minister for Works was passed:—

> That it is expedient that the proposed additions to Prince Alfred Hospital, Sydney, referred to the Parliamentary Standing Committee on Public Works, be carried out, provided that the cost does not exceed the sum of £45,000, and subject to the alterations in the details of the plans as recommended by the said committee.

Some time ago the Board of Public Health in Victoria declined to permit the erection of an infectious ward at the Melbourne Hospital in the place of the tents now used for the purpose. The committee then proposed to erect a non-infectious ward on the site. To this the board also objected as follows:—

> In the opinion of the board the construction of the buildings as proposed would not conduce to the healthfulness of the institution. If it is desired to add to the accommodation of the institution it would appear to be well to consider whether reconstruction could not be entertained so as to utilise the land to the best advantage and to gradually build in accordance with modern principles of hospital construction, and that, if it is felt to be imperative that permanent accommodation be supplied on the site at present occupied by the tents, an area absolutely clear of buildings all round to the extent of at least 35 feet should be provided; also that the board cannot give its approval to the treatment of distinctively infectious cases in any building erected on the grounds of the institution, unless it be one or two cases such as might arise in the institution and be treated in some isolated portion of the grounds.

For some months past improvements have been progressing at the Sydney Hospital. The whole of the old operating theatre has been demolished, except the outside walls, and has been rebuilt on modern principles The nurses' quarters

Fiaschi, T., M.D., Ch.D. Pisa, has been appointed Examiner in Clinical Surgery at the Sydney University, New South Wales.

Flint, T. B., M.R C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Medical Officer to the Devonshire Hospital, Buxton.

Freear, A., M.R.C.S., F.R.C.P. Lond., has been appointed Resident Medical Officer at the Medway Union Workhouse.

Gemmell, James Francis, M.B. Glasg. and C.M., has been appointed Medical Superintendent of Whittingham Asylum.

Hankins, G. T., M.R.C.S., L.S.A., has been appointed Examiner in Surgery at the Sydney University, New South Wales.

Hewer, Cecil M., F.R.C.S. Eng., has been appointed Certifying Surgeon under the Factory Acts for the Tarporley Urban District of Cheshire.

Jones, P. Sydney, M.D. Lond., F.R C.S., has been appointed Examiner in Clinical Medicine in the Sydney University, New South Wales.

Lace, Frederick, F.R.C.S,, has been appointed Surgeon to the Royal United Hospital, Bath, vice F. K. Green, F.R.C.S., resigned.

MacCulloch, S. H., M.B., Ch.M. Edin., has been appointed Examiner in Midwifery at the Sydney University, New South Wales.

Mackellar, C. K., the Hon., M.B., Ch.M. Glasg., has been appointed Examiner in Medicine at the Sydney Uhiversity, New South Wales.

Maher, W. Odillo, M.D., Q.U.I., M.R.C.S., has been appointed Examiner in Ophthalmic Medicine and Surgery at the Sydney University, New South Wales.

Mills, A. E., M.B., Ch.M. Syd., has been appointed Examiner in Anatomy at the Sydney University, New South Wales.

Munro, A. Watson, M.D. Edin., has been appointed Examiner in Materia Medica at Sydney University, New South Wales.

Perry, S. H., M.R.C.S., L.R.C.P., has been appointed Medical Officer of Health under the Rural District Council of Spalding.

Pethybridge, W. L., M.D., B.Sc. Lond., M.R.C.S., L.R.C.P., has been appointed Honorary Anæsthetist to the Royal Eye Infirmary, Plymouth.

Pritchett, S. I., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for the City of Rochester, Medical Officer of Health for the Port of Rochester, and Medical Officer to the Rochester and Chatham Joint Isolation Hospital.

Ray, John Howson, Ch.M. Vict., F.R.C.S., has been appointed Surgeon to the Manchester Children's Hospital, vice Mr. G. A. Wright, F.R.C.S.

Rennie, G. E., M.D. Lond., has been appointed Examiner in Pathology at Sydney University, New South Wales.

Reynolds, F. E., M.R.C.S., has been appointed Temporary Medical Officer for the Stoke Gabriel District by the Totnes Board of Guardians.

Sinclair, Eric, M.D. Glasg., has been appointed Examiner in Psychological Medicine at the Sydney University, New South Wales.

Stirling, E. C., C.M. Glasg., F.R.S., M.D. Cantab., has been appointed Examiner in Physiology at Sydney University, New South Wales.

Terry, George Henry, F.R.C.S. Edin., M.R C.S., L.S.A., has been appointed Honorary Surgeon to the Royal United Hospital, Bath, vice R. J. H. Scott, F.R.C.S. Edin., M.R.C.S., appointed Consulting Surgeon.

Thompson, W. H., M.D. R.U.I., has been appointed King's Professor of the Institute of Medicine in the School of Physic, Trinity College, Dublin, vice J. Mallet Purser.

Twort, F. W., M.R.C.S., L R.C.P. Lond., has been appointed Assistant Bacteriologist to the London Hospital and Medical College.

Woodman, W. J., M.R C.S., L R.C.P. Lond., has been appointed District Poor-law Medical Officer for Chatham.

Wright, G. A., F.R C.S., has been appointed Consulting Surgeon to the Manchester Children's Hospital.

# Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

Birmingham and Midland Free Hospital for Sick Children.—Resident Surgical Officer. Salary £60 per annum, with board, washing, and attendance.

Bolton Infirmary and Dispensary.—Junior House Surgeon. Salary £80 per annum, with apartments, board, and attendance.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon, under the Factory Acts, at Modbury, in the county of Devon.

# Births, Marriages, and Deaths.

## BIRTHS.

Carruthers.—On Jan. 6th, at Halton, Cheshire, the wife of W Hodgson Carruthers, M.D. Edin., of a daughter.

Lee.—On Jan. 10th, at Talbot House, Storrington, the wife of F. W. Lee, M.R.C.S., L.R.C.P., of a son.

## DEATHS.

Carrington.—On Dec. 25th, 1901, at Catherstone House, Battersea-rise, S.W., Dr. William Henry Carrington, aged 45. Also on Jan. 2nd, 1902, at Gloucester, Frederick George, brother of above, aged 52.

Simpson.—On Jan. 13th, at Cotswold, Wallington, Surrey, Frederick Hamilton Simpson, F.R.C.S., aged 87 years.

Taylor.—On Jan. 11th, at Hartington-villas, Hove, John Taylor, M.D. Aberd., M.R.C.P., F.R.C.S., formerly of Queen's-road, Bayswater, in his 84th year.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

BRISTOL MEDICAL CHARITIES.—The employés of Messrs. W. D. and H. O. Wills voluntarily collected during 1901 the sum of £443 for the various Bristol medical charities.

AT the Bath Police-court on Jan. 8th a music-hall performer, was summoned for being in a public place—namely, in the Lyric Theatre—on Dec. 4th, 1901, while suffering from scarlet fever. She was fined 20*s.* and costs.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—On Jan 9th a meeting was held in the Park Hall, Cardiff, on the occasion of the public welcome to Mr. E. H. Griffiths, M.A., F.R S, the new Principal of the University College of South Wales and Monmouthshire.

GIFT TO DUNDEE INFIRMARY.—At a meeting of the directors of the Dundee Royal Infirmary on Jan. 9th it was stated that a gentleman who did not wish his name to be mentioned had offered to supply and to fit up a Finsen electric lamp for the treatment of lupus.

PRESENTATION.—Mr. W. M. M. Jackson, M.D. Mich, L.R C.P., L R C.S. Edin., on resigning the post of resident medical officer at the Westmorland Consumptive Sanatórium, was presented by the patients, as a mark of their esteem and in recognition of the attention which they received from him, with a silver-mounted walking-stick engraved with his initials.

BRISTOL DISPENSARY—The annual meeting of the subscribers to this institution was held on Jan. 10th, under the presidency of Mr. Fenwick Richards. The medical report stated that 10,660 patients had been treated during 1901, compared with 11,410 in the preceding year. The financial statement was satisfactory and showed that a legacy of £500 had been received.

SMALL-POX AT EXETER.—Five cases of small-pox have been notified at Exeter and the board of guardians on Jan. 7th, on the recommendation of the medical officer, decided to suspend the visiting arrangements at the workhouse. Handbills are to be posted about the city stating that persons over 14 years of age will be revaccinated by the public vaccinator free of charge.

BEQUESTS TO HOSPITALS.—The late Mr. J L. Molleson of Edinburgh has bequeathed to the Sick Children's Hospital, Edinburgh, and the Victoria Hospital for Consumption £1000 each, and to the Longmore Hospital for Incurables £2000. The residue of the estate, after certain other bequests, goes to the Edinburgh Royal Infirmary.—By the will of Mr. Charles Cleaver of Birkdale the sum of £100 is bequeathed to the Southport Hospital.

PLYMOUTH ROYAL EYE INFIRMARY.—The annual meeting of the subscribers to this institution was held on Jan. 8th, under the presidency of Mr. H. Serpell. The medical report stated that during 1901 there were 255 in-patients admitted, the daily average number in the institution being 18. The out-patients numbered 1905. The financial statement showed that the income amounted to £1284 and the expenditure to £1169. The committee appeals for subscriptions towards the building fund of the infirmary as there is a balance of £12,000 still to be raised.

LITERARY INTELLIGENCE.—Messrs. Smith, Elder, and Co. will publish shortly a work entitled, "Lectures on Chemical Pathology in its Relation to Practical Medicine," by Dr. C A. Herter, Professor of Pathological Chemistry, University and Bellevue Medical Schools, New York. The book will be issued simultaneously in the United States by Messrs. Lea Bros. and Co of Philadelphia. Messrs. Smith, Elder, and Co. will also publish immediately a fifth edition, revised and edited by Dr F J. Poynton, of Dr. Cheadle's well-known work on the Artificial Feeding of Infants.

MR. W. R. TUCK died at his residence, 1, Windsor-place, Newquay, on Jan. 4th, after a short illness. Mr. Tuck, who obtained the L.D.S. of the Royal College of Surgeons of England in 1863, practised his profession for many years in Truro, where he had an extensive practice and was for many years honorary dental surgeon to the local hospital. He contributed some articles to the medical journals and also published some "Reminiscences of Cornwall." Mr. Tuck leaves a widow, two sons (both members of the dental profession), and four daughters. The deceased gentleman took a great interest in all matters connected with his native county, and by his death one of the oldest, and at one time best-known, residents of Cornwall has passed away.

## BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX, 8, Henrietta-street, Covent-garden, W.C.
The Imperial Health Manual. Being the authorised English edition of the Official Health Manual issued by the Imperial Health Department of Germany. Edited by Antony Roche, M.R.C.P. Irel., &c. Second English edition, revised from the latest German edition. Price 3*s.* net.

*CORNISH, J. E., St. Ann's square, Manchester. (MACMILLAN AND CO., London).*
The Victoria University Calendar for the Year 1902. Price 1*s.*

GOVERNMENT PRINTING OFFICE, Washington.
Index-Catalogue of the Library of the Surgeon-General's Office, United States Army. Authors and Subjects. Second series. Vol. vi. G—Hernette.

KIMPTON, HENRY, 13, Furnival-street, Holborn, E.C.
*Progressive Medicine.* Edited by H. A. Hare, M.D., *assisted by* H. R. M Landis, M.D. Volume iii. September, 1901. Price not stated.

LONGMANS, GREEN AND CO., 39, Paternoster-row, E.C.
Quain's Dictionary of Medicine. By Various Writers. Third edition. Largely rewritten and revised throughout. Edited by H. Montague Murray, M.D., F.R.C.P., assisted by John Harold, M.B., B.Ch., B A O., and W. Cecil Bosanquet, M.A., M.D., M.R.C.P. Price 21*s.* net.

PENTLAND, YOUNG J., Edinburgh and London.
The Edinburgh Medical Journal. Edited by G. A. Gibson, M.D., F.R.C.P. Edin. New series, Vol. x. Price not stated.

STEINHEIL, G., 2, Rue Casimir-Delavigne, Paris.
Formulaire Aide-Mémoire de la Faculté de Médecine et des Médecins des Hôpitaux de Paris. Par Dr. Fernand Roux. Fifth edition, revised and enlarged by Dr. Lemanski. Price 4 francs.

"THE LOCAL GOVERNMENT JOURNAL" OFFICE, 2, Dorset-street, Fleet-street, E.C.
The Local Government Annual and Official Directory, 1902. Officially corrected. Edited by S. Edgecumbe Rogers. Price 1*s.* 6*d.*

WRIGHT, JOHN, AND CO., Bristol.
"First Aid" to the Injured and Sick: an Advanced Ambulance Handbook. By F. J. Warwick, B.A., M.B. Cantab., M.R.C.S., L S A., and A. C Tunstall, M.D., F.R.C.S. Edin. Second edition. Price 2*s.* 6*d*
Elementary Bandaging and Surgical Dressing; with Directions Concerning the Immediate Treatment of Cases of Emergency. For the Use of Dressers and Nurses. By the late Walter Pye, F R.C.S.; revised by Thomas Carwardine, M.S., F.R.C.S. Ninth edition. Price 2*s.*

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ARMSTRONG, W G, M.B., Ch.M. Syd., D.P.H. Camb., has been appointed Examiner in Medical Jurisprudence and Public Health at Sydney

BARRINGTON, FOURNESS, F.R.C.S., M.B. Edin., has been appointed Examiner in Gynæcology in the Sydney University, New South Wales.

BEDDARD, A. P, M D, M R C.P., has been appointed Physician to the West London Hospital, vice Dr. F. G. D. Drewitt, resigned.

BROWNE, T. W. STANLEY, M R C.S., L R.C.P. Lond., has been appointed District Poor law Medical Officer for Chatham.

BROWNLOW, HARRY LURGAN, F.R C.S. Eng., L R.C P. Lond, has been appointed Honorary Assistant Surgeon to the Royal United Hospital, Bath.

BRYAN, H J M R C S, L.R.C.P. Lond., has been appointed District Poor-law Medical Officer for Chatham.

CANT, A, M B, B Ch Birm., M.R.C.S., L.R.C P. Lond., has been appointed Certifying Surgeon under the Factory Acts for the Coleshill District of the County of Warwick

CARRE SMITH, HERBERT, L.R.C P. Lond, M.R C S., has been appointed to the Morley Convalescent Home, St. Margaret's Bay, Dover, and to the Alfred Bevan Memorial Home for Men, Women, and Children, Sandgate.

CATTO, JOHN, M B Ch B Aberd., has been appointed Medical Officer to the Tanjong Pagar Company, Singapore.

COOKE, WILLIAM H F R C S.E., L.R C P, has been appointed Assistant Surgeon to the Royal United Hospital, Bath.

CROWE, D, M.B., B S Dubl, has been appointed Medical Officer for the Ulceby District of the Brigg Union.

### ILLUSTRIOUS MEDICAL MEN.

WE have previously noticed the excellent series of reproductions of famous pictures comprised in the "Vibrona Art Series" of Messrs. Fletcher, Fletcher and Co. of Holloway, N., and quite recently we referred to a portrait of Edward Jenner, the apostle of vaccination, which was the first of a series devoted to portraits of illustrious Englishmen. We have now received two additional portraits in this series—those of John Hunter and of William Harvey. Both are from the original paintings in the National Portrait Gallery and are reproduced in the best style on fine plate paper, measuring about 20 by 25 inches. Their nominal cost, 2*s.* 6*d.* each, post free, is an additional recommendation.

### THE IDENTIFICATION DEPARTMENT AT PRETORIA.

IN an article on the transactions of the Identification Department of the Red Cross Society of Pretoria during the first phase of the war, which appeared in the third fasciculus of *Militar Geneeskundig Tijdschrift*, 1901, Dr. Romeyn incidentally throws light upon the uncultivated, or, indeed, semi-savage, nature of the Boers. When hostilities broke out, he says, the administrative part of the public health service was in a rudimentary state, the lack of organisation depending, among other things, on the character of the burghers who look upon all regulations as attacks aimed at their independence. Moreover, he continues, their sole knowledge of warfare was derived from fighting Kaffirs and they consequently were absolutely ignorant of the obligations and usages which devolved upon them during a contest with European troops. It was not until after the battle of Elandslaagte that the burghers began to recognise the advantages of order and regularity. Owing to the insufficiency of the telegraph service and also to the confusion caused by the multiplicity of homonyms in the Boer ranks, the returns of killed and wounded in that engagement were full of mistakes and omissions. Professor Molengraaf of Amsterdam, the well-known geologist, thereupon prepared a scheme for the organisation of an identification service, and succeeded in obtaining for it the sanction of the Boer authorities. It was desirable that the members of the new service should be recognised as non-combatants, in order that they might enjoy the prerogatives accorded to the class, and so Professor Molengraaf placed himself in communication with the officer commanding the British forces at Capetown, who immediately signified his approval of the project. An important part of Professor Molengraaf's scheme consisted in the distribution among the fighting burghers of descriptive cards—green for the Transvaalians and orange for natives of the Orange Free State—which should serve the purposes of identification, but here again the prejudice of the burghers proved a stumbling-block. They strenuously objected to carry what they called "death tickets," and much time and trouble were expended in persuading them to do so. The Identification Department ceased to exist on June 6th, 1900, the date on which Pretoria was captured. According to Dr. Romeyn the total mortality on the Boer side up to that date did not exceed 1055, "notwithstanding the fantastic figures given by the English."

### LOCUM-TENENTS AND ASSISTANTS' FEES.

MR. PERCIVAL TURNER, writing on the above subject, points out that in "Via Medica," published by Dr. Langley in 1871, page 85, it is stated that the qualified indoor assistant could obtain from £50 to £60 a year, or even £70 or £80, and that an outdoor qualified assistant's salary, without a house, was from £100 a year. Locum-tenents' fees on the same page are given as from £2 2*s.* a week. "In 1895," says Mr. Turner, "£3 3*s.* was the minimum fee for a locum-tenent, and assistants' salaries were proportionally higher; now in 1902 the recognised minimum is £4 4*s.* a week, which seems a fair remuneration in the majority of cases. Has the general practitioner been able to raise his fees of late years in like proportion, or has he not rather, by medical aid associations, cheap dispensaries, and other questionable associations, been compelled to lower his charges?"

### "THE TUBOR FILTER."

THE Berkefeld Filter Co. (121, Oxford-street, London, W.) has recently introduced an improved germ-proof filter which is to be distinguished by the name "Tubor." According to a series of bacteriological experiments quoted, "these filters may be regarded as perfectly safe and can be depended on to give a sterile filtrate for four or five days," after which it is desirable that they should be cleaned and sterilised.

### X RAYS IN CANCER.

*To the Editors of* THE LANCET.

SIRS,—I would be very grateful if any of your numerous readers could inform me through your columns of the best and latest methods of applying the x rays in the treatment of cancer. I would also be glad to know of any literature on the subject and where the same could be obtained.

I am, Sirs, yours faithfully,

ANXIOUS PRACTITIONER.

Jan. 13th, 1902.

MESSRS. SOUTHALL BROS. AND BARCLAY of Birmingham have forwarded us a copy of their tenth annual laboratory report which contains many matters of interest and importance to pharmacists. The sections dealing with the uniformity of galenicals, standards for concentrated infusions, tinctures, &c., are examples. The report is evidently based on a considerable amount of laboratory work.

◆

*Dr. F. H. Alderson (Bournemouth).*—We have forwarded the subscription to the honorary secretary of the R. B. Anderson Fund, Mr. Walter Monnington, 7, Fig Tree-court, Temple, E.C.

ERRATA.—In our "Analytical Records" in THE LANCET of Jan. 4th (p. 36) the heading "Zoeco" should have read "*Zoeco*" *Milk Proteids with Cocoa.* The manufacturers point out that the word "Zoeco" is used only as a brand name.—Dr. J. F. Gemmel, whose appointment we noticed last week (THE LANCET, Jan. 11th, page 124, line 17, etc., column 1) as medical superintendent of Whittingham Asylum, is senior assistant medical officer of *Lancaster* (not Prestwich) Asylum.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## Medical Diary for the ensuing Week.

### OPERATIONS.

#### METROPOLITAN HOSPITALS.

**MONDAY** (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.) square, W.).—8.30 P.M. Dr. W. Cayley: A Case of Phlegmono
Gastritis due to Streptococcic Infection.—Mr. A. G. R. Foulerto
A Case of Pneumococcic Gastritis with General Infection.—Mr.
Spitta: The Bacteriology of a Case of Rapidly Spreading Gangre
—Dr. Bulloch: The Transmission of Hæmolysins from Ascendar
to Descendants.

CHELSEA CLINICAL SOCIETY (Jenner Institute of Preventive Medici
Chelsea-gardens, Grosvenor-road, S.W.).—8.30 P.M. Communi
tions:—Mr. L. A. Bidwell: Cases of Empyema of the Gall Bladd
—Dr. J. B. Ball: Remarks on the Clinical Diagnosis of Diphthe
in Relation to Treatment.

**WEDNESDAY** (22nd).—DERMATOLOGICAL SOCIETY OF GREAT BRITA
AND IRELAND (20, Hanover-square, W.).—5 P.M. Meeting.

SOCIETY OF ARTS.—8 P.M. Rev. J. M. Bacon: Scientific Observatio
at High Altitudes.

HUNTERIAN SOCIETY.—8.30 P.M. Dr. A. Chaplin: The Treatment
Pleuritic Effusion.

**THURSDAY** (23rd).—SOCIETY OF ARTS.—4.30 P.M. Mr. F. H. Skrin
Bengal, the Land and its People.

# Notes, Short Comments, and Answers to Correspondents.

## MEDICAL AID ASSOCIATIONS AND THE GENERAL MEDICAL COUNCIL

*To the Editors of* THE LANCET.

SIRS,—I take it as extremely kind of your correspondent Mr John MacCormac in THE LANCET of Jan 4th, p 65, that he should with a rapidity of perception and lucidity of exposition which are remarkable epitomise my arguments in so few words and at the same time confer upon me the wish to champion the cause of the unqualified assistant and the medical aid associations Apparently he misunderstood the trend of my letter, but I am not responsible for that, and it was not written for the purpose of provoking an argument with him but with the object of drawing attention to the bungling methods of the General Medical Council and to its want of practical acquaintance with the requirements of the general practitioner The treatment of the unqualified assistant, the medical aid associations, and the Midwives Bill were given as instances, but there are others What of the poor fellow with the M D Brux , L S A Lond , who was persecuted and ruined? and what of the latest piece of tyranny in connexion with the medical officer of the Liverpool Victoria Friendly Association and its qualification of his conduct? Did the means in these cases justify the ends and were the ends obtained just? Truly, as Mr MacCormac says, "the duty of the General Medical Council is to protect the public", it is. And unfortunately so for the practitioner As for the unqualified assistants many had to go without notice, no probationary period being allowed, but what of that?—their places have been filled, by a different class of man, I grant—the *bonâ fide* medical student, but still unqualified, and I fail to see the difference between one unqualified man and another. With regard to the medical aid associations it is easy to take the usual stereotyped idealistic view, but that does not explain why the attendance on a working man who pays his 1*d* or 2*d* a week is more dishonourable than a similar attendance at a large hospital which he supports in the same fashion and which he cannot be blamed for taking full advantage of; and it is no nearer and offers no help to the solution of a problem which will have to be solved, and which will require the application of practical common sense and will be in no way affected by idle contempt or high theoretical ideals As for contract works and their not being science, are not all Poor law appointments, most large schools, works, &c —are not these contract works, and on no better scale of pay than medical aid associations? Is not one case as interesting as another, whether it be a contract or a private case? And as for their being ' humbug,' would your correspondent if he were appointed surgeon to some large works and were receiving 1*d* a week per head from 1000 workpeople —would he be pleased if that appointment were cancelled and that money handed over instead to some large charitable institution as a gift but to constitute a lien on its services, as is being agitated for to my knowledge? I pass over references to my youth—age does not always signify wisdom; also the views in general on the *locus standi* of the club medical officer with his patients—they can be taken for what they are worth , but I would point out that there are institutions which should be modified and not crushed, that there are abuses which properly treated may be transformed into usefulness, that the General Medical Council's methods whilst being satisfactory to some are not so to others, and that even a club medical officer has opinions and rights, and if he cares to use it the power to see that those rights and opinions are treated with respect Moreover the General Medical Council is, or should be, the servant and not the despotic master, and it is time it learnt that fact With apologies for space,

I am Sirs, yours faithfully,

Jan 8th, 1902 HARRY CLOUGH.

*To the Editors of* THE LANCET

SIRS,—I was glad to read the letter of Mr Harry Clough in THE LANCET of Dec 28th, 1901 p 1848 I will go further and say that it seems quite time something should be done to put a check to the methods lately adopted by the General Medical Council and the very harsh treatment meted out by that body to the less fortunate members of our profession I, in common I suppose with all qualified medical men, hailed with satisfaction the decision of the General Medical Council to suppress unqualified practice—that is, the practising the professions of physician surgeon, or accoucheur by gentlemen without a diploma on their own account But the Council went further and deprived of their living a deserving class of men—I refer to men of middle age, who through no fault of their own, and owing to circumstances over which they had no control were unable to obtain their diplomas and registration but who as assistants acquired a thorough knowledge of their profession and experience not only in the treatment *of disease but in the management of patients, the latter qualification* being most important, especially in large country practices, and these laws were passed, so the Council say, ' to protect the public," that is our patients, from the unskilled treatment of the unqualified At the same time (and this seems to be the absurd part of the whole matter) we are permitted the Council to employ as *assistants and locums and to place the lives of our patients* (the public) in the hands of young men, boys of 26 or 27 years of age just qualified who can have no practical knowledge, or, at least, very little, and, of course, without any experience in the treatment or management of even ordinary illnesses and complaints , the result, of course, being that on the return home of the principal he finds not only his practice ruined, but many of his patients wrongly and unskilfully treated not through any neglect but simply through want of knowledge in the young locum Then with regard to young club doctors, the action of the Council lately seems unduly severe No practitioner would of choice become a medical officer to a club or a medical aid society , it means hard work, drudgery, and very poor remuneration. But there must be a beginning and it seems hard that because a man applying for such a post should solicit the aid of his friends and neighbours he should be accused of "infamous" conduct and threatened by the Council with expulsion from the profession, which means that he must adopt some other means of living or go to the workhouse Lawyers as well as medical men canvass—they must do so—for public appointments such as coronerships appointments under the Local Government Board such as Poor law, &c , and their conduct is not considered "infamous ' There ought to be an appeal in law from these tyrannical decisions of the General Medical Council, and until there is the only course open to medical men who consider themselves wronged is to consult their M P 's and to have the matter brought before Parliament I am, Sirs, yours faithfully,

Dec 31st, 1901 FAIRPLAY

*To the Editors of* THE LANCET.

SIRS,—The following is a copy of a circular letter being sent to the medical practitioners of the district in which I live

I am, Sirs, yours faithfully,

Jan 10th, 1902 ONE OF THEM

[COPY.]

' "Dear ——,—An attempt having just been unsuccessfully made to induce a medical practitioner of this town to examine and attend people for a canvassing association for medical aid by means of the false assertion that three other medical men—whose names were given—had already consented to act in that capacity, I acquaint you of the fact and can show you the correspondence and disclaimers if you wish It is to be expected this exposure will prevent another insidious attack from being made on our status; the more we present a united front against our foes the easier it is for all of us to support the recent notice about medical aid associations from the General Medical Council

I am, dear ——, yours very faithfully,

December, 1901 ——

## FEES FOR INSURANCE EXAMINATIONS

*To the Editors of* THE LANCET

SIRS,—In THE LANCET of Dec 14th, 1901 p 1710, "Cyclops" comments upon the Century Insurance Company sending him 10*s* 6*d* —half his usual fee—for an "unusually rigorous' medical examination and full report, in which "about 60 questions had to be answered ' In THE LANCET of Dec 21st 1901, p 1776, the manager of the aforesaid company alleges ' grave mis statements From my own experience of medical examinations for the same company I can confirm "Cyclops" as to the questions being "about 60' and not 10 Moreover, "full and specific answers are particularly requested," thereby indicating an examination careful and thorough, as it always should be It seems immaterial as to how many sides of foolscap or of some other sized paper the questions fill up, but as to fees Mr H Brown has sometimes sent me 5*s* for similar examinations, and he must expect protests (useless no doubt) even as to the 10*s* 6*d* "fixed by the medical advisers ' he says It does seem strange that the company which he advertises as specially adapted to the needs of medical men "should be conspicuous in endeavours to underpay them As one who knows, I would strongly urge medical men, before completing an assurance against sickness to examine carefully and note the conditions and restrictions of a sickness policy, as well as the prospective contingent benefits I am, Sirs, yours faithfully,

Dec 30th, 1901 VIGILANS

## MEDICAL SOCIETIES

*To the Editors of* THE LANCET.

SIRS,—I should be glad of your valuable opinion and advice on the following matter. A proposal was set on foot to establish a medical society in our village and a circular was sent round stating that "every registered medical practitioner in the place and district is eligible for admission and the election is by ballot." 17 out of the 19 resident practitioners have been elected or have elected themselves, members The two who have been excluded are on the Medical Register It is stated that on no account will they be admitted as members The objects of the society are said to be to promote unity of action and the interests of the profession Perhaps you will be so kind as to inform me whether this is the usual procedure in the formation of similar societies and whether in your opinion it is likely to attain the ends aimed at Yours faithfully,

Jan 13th, 1902. ENQUIRER.

⁂ We cannot give any opinion, but we may remind our correspondent that although a man may be eligible for election to a club or society it does not necessarily follow that he will be elected —ED. L.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1901, which was completed with the issue of Dec. 28th, and the Title-page to the Volume, were given in THE LANCET of Jan 4th.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year | £1 12 6 | One Year | £1 14 8 |
| Six Months | 0 16 3 | Six Months | 0 17 4 |
| Three Months | 0 8 2 | Three Months | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

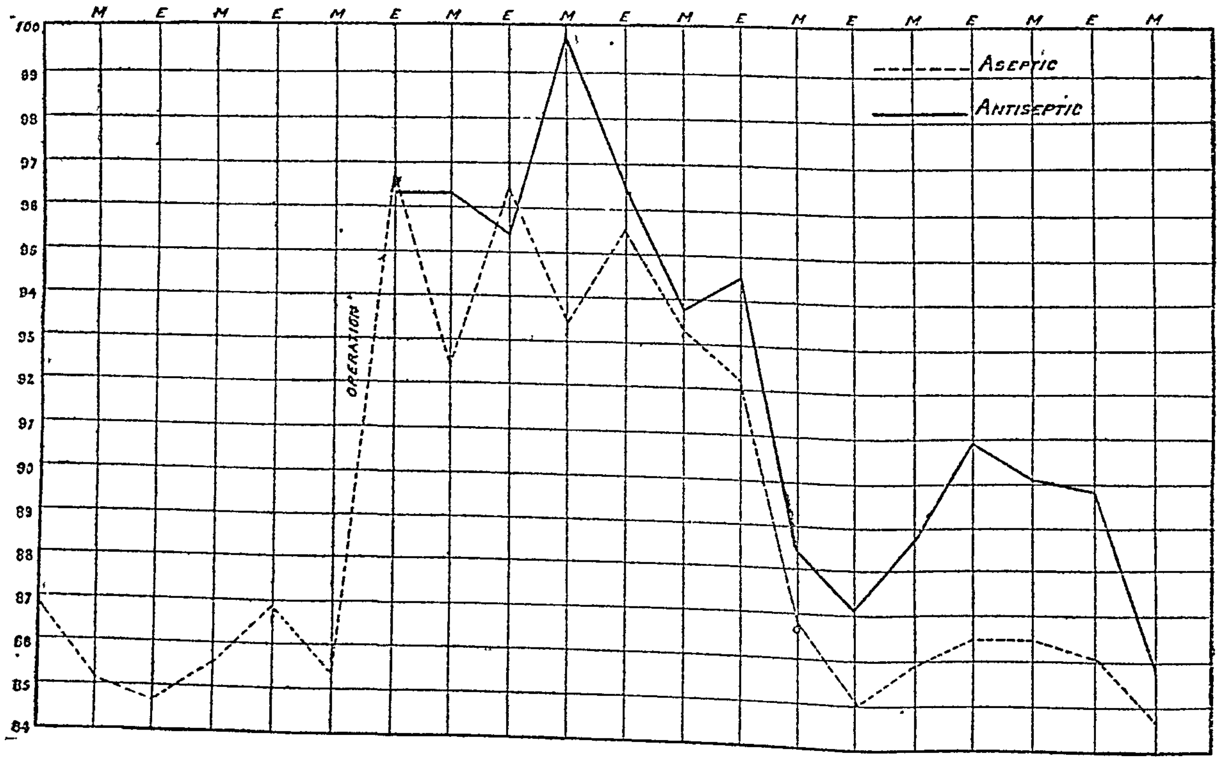
> most costly drugs, nutritious diet, &c.; likewise the house will be crowded with the most miserable objects, to the anxiety of those that attend them, and the exclusion of other patients, who might have been cured in the interim. Many hospital-surgeons are under the necessity of providing lodgings in the country, at their own expense, for their patients who have undergone operations; rather than suffer the pain of a disappointment in completing a good cure or seeing their patient languish under a hectic, incurable in a crowded Infirmary. Therefore it is hoped that these considerations will influence the humane Trustees, to provide these conveniences for the poor sufferers.

I think, gentlemen, that although my quotation has been rather a long one, yet it is a most interesting thing to remember that these remarkable suggestions were made 120 years ago by Edward Alanson, surgeon to the Liverpool Royal Infirmary, and I doubt whether they could be improved upon at the present day; we are not yet able to say that all the improvements indicated by him have been accomplished. He was indeed in advance of his time and was very near the truth as it appears to us to-day. The main point that strikes one is the great importance which he evidently attaches to the part played by the air in the spreading of infection. We think less of the air and more of the hands as infection-spreaders. We think less of infection and more of contagion. This seems a small difference, but it is a fundamental difference in principle, which is responsible for nearly all that divides our present work from that of 100 years ago. Owing to our better hospital construction the want of ventilation, &c., has been removed from our list of enemies and we can confine our attention to the dangers of contact. So much for the first period.

FIG. 1.



Mean pulse chart of 80 cases of abdominal section—40 aseptic and 40 antiseptic.

The second period, or the antiseptic stage, is so recent that it is not necessary to recall what is known to everybody. In the short period of 20 years or little more a complete revolution in surgical methods has taken place, and it would hardly be exaggeration to say that in that time we have passed from night into day. For although there must be much to learn and to simplify in the future, yet when we compare the methods of to-day with the methods of 20 years ago we may almost say that we are now already in the full light of noonday. I well remember an incident which happened when I was a dresser, not such very remote ages ago. It made a great impression on my mind at the time, and I have often pondered over it since. To us to-day it sounds like a story of the Middle Ages. A man was brought into hospital having fractured his patella. At about this time Mr. Lister had been suggesting wiring together the fragments as a method of treatment. My chief said that he thought this case would be a suitable one on which to try the new method of treatment, and it was arranged that the operation should be performed upon the following day. We all forthwith went down into the post-mortem room and practised this new operation. There was one gimlet which pierced the bone in a marvellously easy way, in a way that none of the others would. The surgeon naturally said, "We will use that one to-morrow," and we did. The operation was performed on the following day in a most masterly fashion, under a cloud of carbolic spray and (according to the notes) "with the strictest antiseptic precautions." Things went wrong, however, and the man died from septicæmia. The gimlet had killed him. But the antiseptic system and the new operation were blamed at the time. We have learned much since then, and it seems remarkable to us now that anyone could be so blind; but it is well to remember that the men who appear to us so blind were the leaders of the profession and the most advanced men of the time, and we must expect to appear just as blind to the next generation.

We are now passing from the antiseptic period to the non-antiseptic or aseptic period, and if we do not attain the results that have been attained by some we should not at once blame the system, but carefully criticise our own technique and remember the story of the gimlet.

It is hardly necessary to say that when I use the term "aseptic surgery" I use it in the sense of being without antiseptics. I do not care for the term, but I do not know a better unless we borrow a term from medicine and speak of "prophylactic" or "preventive" surgery. The term "preventive" would indicate the principle which underlies our present practice. There always seems to have been a fascination for the surgeon to put something into his wound to make it heal better. In the pre-antiseptic days at one time it was the fashion to fill the wound with boiling oil, at another the wound was stuffed with dry lint and freely dredged with flour, and many other devices were employed. In the antiseptic period wounds were douched and swilled with antiseptics and sometimes filled up with iodoform. In the aseptic method there is nothing put into the wound to irritate it or to help it to heal; the object is to keep out all that is detrimental to healing.

Aseptic surgery is a stage onwards towards the goal of perfect surgery. We all hailed antisepsis, and now we should all hail asepsis. Antisepsis naturally came first and

# A Presidential Address

ON

# THE PROGRESS OF SURGICAL METHODS.

*Read before the North of England Obstetrical and Gynæcological Society on Dec. 20th, 1901,*

BY T. B. GRIMSDALE, B.A., M.B. CANTAB.,
GYNÆCOLOGICAL SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

GENTLEMEN,—My first duty is to thank you for the honour which you have done me in electing me to be your president. I need hardly say that it is an honour which I appreciate very highly; and since you have made me your president there is a pleasant duty which devolves upon me, and that is to address you on some subject connected with gynæcology. It is unusual at such a time for the reader of the address to be interfered with or criticised, so that the president can say what he likes without much fear of contradiction. This, of course, is a great distinction and at times it may be felt to be a great advantage; it at least shows the trust and confidence which the society has in its presidents, but as we all have the same object at heart, the advancement of gynæcology, I think that it is rather a pity that criticism, tempered with leniency, is not the rule. On this occasion if any one of my audience feels inclined to criticise my remarks, although it would be contrary to precedent, I shall not rule him out of order but shall take it as a compliment and a sign that I have managed to interest him.

In casting about for a subject on which to address you I have not looked very far afield I have taken the subject which appears to me to be the most important and which looms largest in the mind of the operating surgeon. It is the Progress of Surgical Methods—one might almost say the revolution in surgery. This is a theme upon which much has been written, and although I can hardly hope to add anything to this great subject, yet, however feeble my tribute, I feel that I must lay my homage at the feet of the great master of our art, Lord Lister, and pay reverence to the memory of that great Frenchman, Pasteur, from whom Lister's first inspiration was derived When one considers the anxieties, the nervous strain, the bitter disappointments of the earlier surgeon, the horrible sufferings of the patient, which were sufficient to make the life of the surgeon a terrible ordeal such as few could endure, one cannot help feeling a spirit of devout thankfulness for the privilege of having lived after Lister's epoch-making discoveries

There are three stages in the progress of surgical methods which I propose to touch upon; they are very striking and are significant of the theory of the method of healing of the day. These three stages are. (1) the open method period; (2) the drainage-tube or vent period; and (3) the period of complete closure. These three stages, of course, correspond with the pre-antiseptic, the antiseptic, and the aseptic periods. In the first of these periods suppuration was supposed to be inevitable and was encouraged by the surgeon. It was considered that the wound must be "digested" before it could heal and the wound was left open to accord with this theory. In the second period suppuration was expected and a vent was left for its exit. In the third period the presence of suppuration denoted failure. It was not expected and the wound was completely closed.

As illustrating the results obtained during the first period, when the open method of treatment was in vogue, I will quote the results of amputations performed about 100 years ago, as stated by Alanson, one of the members of the staff of the Liverpool Royal Infirmary at that time. Alanson was a man of great originality, a most careful and successful surgeon, and an observer of great intelligence. He was much in advance of his time and was the inventor of "flaps" in the amputation of limbs. He says:—

> Of 46 amputations at which I was present and had the opportunity of inspecting the after-treatment, 10 died; one of the lockjaw; two of hæmorrhage from the whole surface of the stump; four from the hectic fever and extensive suppurations; and three from a spreading gangrene on the surface of the stump 18 had a hæmorrhage, six from the whole surface of the wound, and 12 from a particular vessel or vessels. In nearly the whole, the symptomatic fever was violent; the startings and spasms frequent; the suppuration large; the surface of the wound extensive; and in all the first dressings were painful In most of them, there was an exfoliation; and in several a sugar-loaf stump; and in some the wound remained incurable.

I will not read any account of the operations, but were I to do so you would not be surprised at the results being poor. If along with this you consider the material upon which the operations were performed and the enormous disadvantages under which the surgeon laboured you would wonder that any patients at all recovered. Of course there was no anæsthetic, and the patient, fearing the pain of operation, would put it off till he could go on no longer. The hospitals also were not all that could be desired. In spite of all this, however, Alanson performed 35 amputations with no mortality. As far as mortality goes these results of Alanson would compare with those of the present time, but the method and ease of recovery would be very different. He himself mentions incidentally a patient's remark "that the first dressing was worse than any part of the operation." Alanson's results were due to individual genius and care and did not at all represent the general results of the surgical community. Unfortunately at that time there was no North of England or other medical society at which Alanson could enunciate principles to enlighten the world; he was merely able to do better work than his contemporaries and he wrote a book. Having no microscope he was not in a position to prove by actual demonstration the soundness of his principles, although his results showed the value of his methods. His teaching was in consequence forgotten. Before passing on I should like to quote some of Alanson's observations on hospital management, which will give you some idea of the genius of the man and the difficulties which surrounded the surgeon of those days. He says:

> Many hospitals are so tainted by unwholesome effluvia, that they are rather a pest, than a relief to the objects they contain. The following regulations are humbly recommended to the consideration of those, who have the care of hospitals in want of such attention. 1. No ward should be inhabited for a space of more than four months together; for it is impossible to keep a room healthy, that is constantly crowded with diseased people, the walls should be scraped, whitewashed and every other necessary means used for the purification of the air, before the re-admission of patients 2 The bed stocks should be made of iron, to prevent the lodgement of vermin and the more easy absorption of putrid matter. 3. The bedding should be more frequently changed, than is usually done; the bed-tick stuffed with chaff, hay, cut straw or materials of such easy expense, as to admit of their being frequently changed. 4. Where the hospital is conveniently situated for the purpose, all the patients that are able, should carry out their bedding and expose it in the open air, for several hours every day, when the weather permits 5. On the days of admission, those patients that have inhabited foul ships, jails, cellars or garrets, workhouses or other infected places; or whose clothes are dirty, or suspected to contain vermin, before they are suffered to appear in the ward, should first be stripped, and washed in the warm bath, and afterwards clothed with proper dresses, provided at the expense of the Charity by which means the evil of importing infection, so detrimental to the salubrity of every hospital, would be greatly remedied.[1] . 7. The infected clothes should be baked in an oven constructed for the purpose; by which all vermin and infection will be destroyed; and the clothes may be returned clean to the patients, when they are discharged the Hospital. 8. The patients, when received on the days of admission, should be placed in the wards that have been last ventilated, and not in those, that have been long inhabited, where it may reasonably be presumed, the air is considerably tainted. 9. All incurable or infectious cases should be refused admittance; and amongst these should be classed old chronic ulcers of the legs, and particularly those in which there is great loss of substance, for these seldom remained long healed; hence most Hospitals are so crowded, that the intention of the Charity is perverted, as the air is rendered unwholesome. 10. All offensive, gangrenous, or other putrid sores, should be placed in distinct rooms provided for that purpose; and not suffered to taint the whole ward. 11. There should be particular rooms provided for those patients who are the subjects of operations; they should be in the most airy situation, never long inhabited and alternately cleaned and ventilated, as before advised. 12. A Hospital should never be crowded on any account; and always of so large a construction, that some part of the building may at all times be uninhabited, for the purpose of whitewashing, ventilation, &c. 13. When any person has been afflicted with a putrid disease or confined to bed for a length of time, let the bed be emptied, and the bed-stocks, the bed, the sheets, and other linen be washed, and the rest of the bedclothes exposed for some time in the open air, and baked in the oven before they are used again. 14. Let the nurses see that every patient's hands and face are washed every morning; and their feet, once a week. 15. Let the nurse of each ward be liable to a fine, to be deducted from her wages, if some of the windows in her ward are not kept open, during a stated number of hours every day. 16. To every Infirmary, particularly where the wards are crowded, a house in the country, well situated, and at a convenient distance, should appertain; without such assistance many of the patients must perish, which would be easily and certainly preserved; and it will be found, (as may without difficulty be demonstrated) the best policy in the Trustees of an Infirmary, to provide such an appendix. By such assistance patients may be speedily cured, at a small expense; but, if suffered to remain in the Infirmary, their recovery will either be prevented, or obtained in a great length of time, at a considerable expense, by the

---

[1] The sixth regulation which applies to the dresses need not be given.

the results of other operators. I consider that my antiseptic composite chart is very good, but the aseptic chart is better. You will notice that in both series on the fourth morning after operation the patient is well; the pulse and temperature have returned to the normal. There are other points which I cannot show you graphically but of which I feel fully convinced in my own mind. There have been less pain and less trouble from flatulence after operation, and I think that the scars are less inclined to be keloid. I have no doubt that the general comfort of the patient has been increased. These results have been most gratifying to me, and in presenting them to you I have endeavoured to avoid anything like high colouring. I trust that I have not rendered them colourless, but Pope's lines have all along been in my mind:—

> "To observations which ourselves we make
> We grow more partial for the observer's sake."

---

# An Opening Address

ON

# THE ART OF CLINICAL MEDICINE AND ITS TECHNIQUE.

*Delivered before the Students' Medical Society of the Leeds Medical School on Oct. 18th, 1901,*

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN.

GENTLEMEN,—My sense of the honour of your invitation to address you to-night, if it can be equalled by anything, could only compare with the pleasure of finding myself among you in the congenial and invigorating atmosphere of a students' debating society, an old student among those of youthful aspirations and promise, for a semi-confidential talk on matters of intimate concern to us all. To this society, among all other students' medical societies, it is now my privilege to wish every success. The secret of their usefulness and attraction is largely the same as that which facilitates the successful study of clinical medicine and which is also fundamental to the position and dignity of the medical confraternity—collaboration and mutual help: every man contributing his share and ever ready to help his fellow in the joint service of suffering humanity. There is another feature in students' medical societies which suits our subject—it is their universality. Clinical medicine itself is all-embracing. It claims not only a relationship with various kindred sciences but also their constant service. All the work of this prosperous and progressive medical school practically tends to one end, which in my experience has been thoroughly fulfilled—the making of good clinical men. Although, therefore, in offering any clinical advice in this place I feel guilty of bringing coals to Newcastle, your liberality will discern that this fault is inherent to my theme rather than to my intention.

On the subject of clinical art I cannot spare you the infliction of a few true aphorisms. It was the art of clinical medicine which drew from the greatest of physicians the pathetic utterance equally descriptive of all human art—"*Ars longa, vita brevis.*" To the present day it remains the longest of arts and therefore its study must claim the largest share of our time.

"The ideal is the soul of art." This aphorism, though it might seem to be hardly opportune, underlies the whole of our practical purpose to-night. It declares our belief that clinical medicine is eminently progressive and that a brief consideration of some of its tendencies and some of the conditions of its future advance is, perhaps, a pardonable digression. Imagination, that humble "occasional helper" of science, is art's principal handmaid; and it may not be altogether idle to dream of those possibilities which are not yet fully within the reach of this generation.

"*Ars imitatio naturæ.*" This is above all others the clinical aphorism. Half the secret of the clinical art is the correct observation of nature, the other half its successful imitation. But I must not dwell upon that important topic, but at once draw your attention to another aphorism most intimately connected with the purpose of this address—"All art consists of the technique and of the production."

The work of art brings into free play man's highest intellectual and physical attributes; but only provided they have been liberated by patient practice from all mechanical struggle with the accidents of technique. These two components of art are not only distinct but are in some respects in glaring contrast. Nothing could be more prosaic, mechanical, and laborious than the study of technique which is to furnish the ideal with its incarnation. All this is strikingly exemplified in the study of clinical medicine, and the distinction between the technique and the performance is one which it will repay you to grasp at the earliest stage.

I have dwelt upon points of resemblance. In one respect clinical medicine differs from all other arts. Perfection such as is achieved by other artists is denied to us. Our task almost passes the wit of man. It is that of remedying damage and disturbance in a machine of unimaginable complexity. A few hard facts are supplied to us by the sciences; and in addition to these, our scientific facts, there are the so-called great principles of medicine, most of which are empirical postulates and cannot take rank with experimental evidence, but nevertheless are of immense practical value. These are our assets; but when the balance is struck the sum of our actual knowledge is vastly inferior to that of the unknown and perhaps of the unknowable. In other words, our art is an amazing combination of strict knowledge and of absolute ignorance, of minute accuracy and of immense vagueness—it is an art of sciences and an art of the unknown.

But there is a greater inconsistence. Though we confess our ignorance we are as practitioners not allowed to plead it as an excuse. Where life is trembling in the balance something must be done, and our patient expects this something to be the right thing. To act for the best in spite of pervading ignorance is indeed an art. Let it, then, be no slur upon clinical medicine that it is eminently versatile, that it looks all around for help, and that, when it is deserted by science, in its distress it should call imagination to its aid and should not shrink from consulting empiricism. Empiricism and science are a powerful combination. Traditional empiricism—the accumulated experience of countless generations of untrained observers—although hardly as trustworthy as the unthinking instinct of animals, still is a mine of treasure which has only begun to be worked with the searchlight of science. Happily in the perplexity of many counsels we fall back upon the great clinical precept, "*Non nocere,*" and though science may fail us there is one ever-trusted guide, "*Imitatio naturæ.*" The methods adopted by nature are our standard and the test of the safety of our tactics. In spite, then, of our ignorance our treatment may still be of the best if we can succeed in reading nature, not only in a general sense, but nature as she presents herself in the individual patient, and in acquiring that insight which the laity so aptly describe as a knowledge of the patient's constitution.

## MEDICAL EDUCATION, PAST, PRESENT, AND FUTURE.

If I may use the privilege of this debating society to discuss debateable questions, the following considerations may be of interest and perhaps of indirect service.

There are two prominent signs of the times. The first is the rapid and irresistible expansion of science in clinical medicine; to this the public mind has been effectually awakened, and patients not only desire but claim to be treated with all the resources of science. This tendency in therapeutics is reflected in medical education; and practical shape is now being given to it by the growth of the idea of the clinical laboratory, probably the most important element in the clinical system of a near future. No less significant is the other contemporary innovation—the post-graduate system, which symbolises the need which is felt for more clinical instruction. The extraordinary sacrifices made for the sake of further clinical opportunities by members of an overworked profession illustrate the urgency of that need. These two tendencies give special prominence to the prevailing dissociation between the science course and the clinical course to which further reference will be made.

History is full of teachings. Looking back 150 years ago, prior to the birth of modern science, we find the simplest expression of medical education on the pattern of the mediæval trades and guilds—a practical training beginning at an early age—and a course of theory as a finish for maturer years.

was the means by which we were able to advance the art of surgery so enormously that satisfaction and gratification beyond the dreams of the most sanguine were gradually realised This satisfaction has been so great that some are even still complacent with surprise at the marvellous results However, after this first surprise at unexpected successes, there has risen gradually a feeling that perhaps there may be something even better still something to criticise even in the best results yet attained by the antiseptic method, marvellous as these are when we compare them with the results of a short time back.

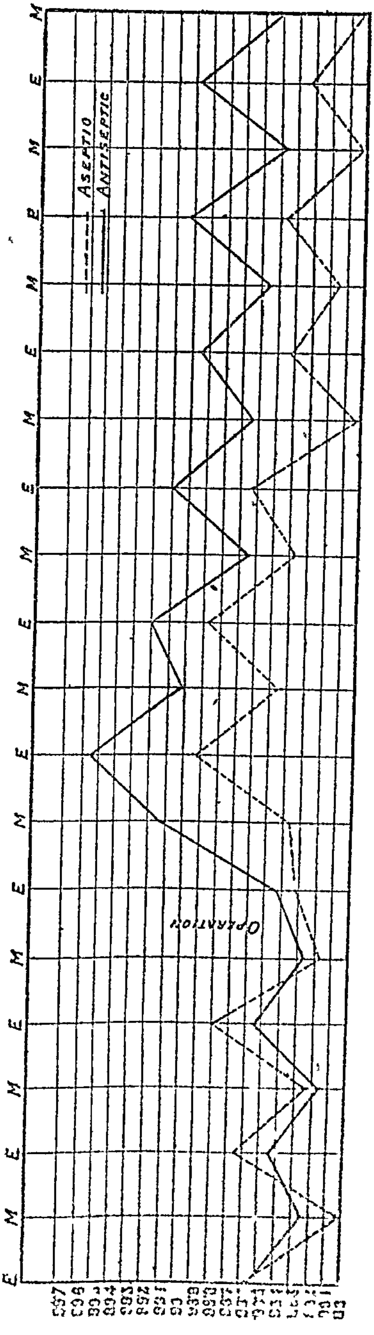
And so we come to the third or aseptic stage and there is no doubt that this is a decided step in advance of the antiseptic stage and the advance is measured by the ease of recovery after operations Of course there has been gradual and decided improvement since the antiseptic stage commenced, and the results at the end of the antiseptic stage became so good that we cannot expect a startling improvement at the commencement of the aseptic stage similar to that at the commencement of the antiseptic stage Further, we must remember that the actual change is only comparatively slight from the end of the antiseptic method to the commencement of the aseptic method The chief difference is a difference in principle indicated by the term "preventive' However, in spite of all this I think that there is a distinct improvement in the results that I have obtained by the aseptic method over anything that I have obtained by the antiseptic method.

I do not propose to enter into minute details of my present method of operating but I will merely say that I now use no antiseptics whatever during operations When the operation commences all antiseptics are laid aside and where formerly I used antiseptic lotions and antiseptic dressings I now use sterile water and sterile dressings I do not allow any antiseptics to get into my wounds The skin of the patient and the hands of the operator and assistants are prepared most carefully with antiseptics but as soon as the operation commences no further use is made of antiseptics The method of hand cleaning which I adopt is the permanganate and oxalic acid method This method is most satisfactory and has stood some very severe tests that I have subjected it to Cleaning hands by this method certainly takes some time—about 20 minutes—but I am sure that it is time well spent and that you are amply repaid for it. In my operations we take every preventive precaution that we can think of to ensure asepsis but as these details would necessarily be tedious I shall not allude to them further in place of detail I will express a sentiment which is I think true and useful The success of the operation depends upon the preparations for its performance—that is upon the completeness and efficiency of the prophylaxis The comparison which I have made between a series of antiseptic operations and a series of aseptic ones certainly has been all in favour of the aseptic series

In order to show the results of the above-mentioned series graphically I have constructed two composite charts and my thanks are due to my house surgeon Mr O I Williams for the help which he has given me in drawing these up

The charts (Figs 1 and 2) represent 80 cases of abdominal section—40 antiseptic operations and 40 aseptic operations The black line marks the antiseptic series and the broken line the aseptic series The charts were made in the following way The pulse and temperature in each case were recorded twice daily, at 10 A M and at 6 P M The record on the composite chart was obtained by adding together the records on the individual charts of each series and dividing by 40 to get the mean The mean pulse and the mean temperature in each series are given on the charts for three days before and a week after operation (In the antiseptic series there is no record of pulse before operation ) You will notice that the broken line representing the aseptic series is always inside the black antiseptic line this denotes an easier recovery after operation in the aseptic series In looking at these charts you may be inclined to say that there is a greater rise in pulse and temperature than you would expect and that your own results would be better than those which I show you but you must remember that these composite charts include all cases bad and good easy or difficult and this is the mean of the whole lot I could show you individual charts in the antiseptic or aseptic series in which there was no rise of pulse or of temperature whatever but this is beside the point, what I want to show is that there is an average improvement in the aseptic series and that it is an improvement on results which will not compare badly with

FIG 2



Mean temperature chart of the same 80 cases as in Fig 1 subjects—viz., of those parts which have an essentially clinical purpose—into the third and fourth years. This would be a step towards associating, instead of dissociating, practical clinical and scientific work, as the higher science training outgrows the narrow compartment of the preliminary curriculum. For instance, the clinical part of physiological chemistry and the study of the blood might be included with other subjects in the course on clinical technique, so that in the future perhaps such terms might be used as "elementary and advanced clinical physiology." Changes as great as this have taken place, and yet greater changes must come. A course of higher applied physiology in the fourth year would tally with the advanced teaching of anatomy in connexion with operative surgery. There is some anomaly in placing before mere tyros the most advanced problems while such simple practical physiology as the auscultation of respiratory and cardiac sounds or the viewing of the fundus oculi or of the trachea is thought too great a departure from the theoretical subjects As regards anatomy, so much laborious knowledge is now quickly lost and unutilised that there would be no detriment in the first instalment being reduced on strictly utilitarian lines and this working minimum gradually added to during subsequent years and developed mainly in the clinical directions of visceral medical anatomy and of operative surgery. On some such plan a portion of the burden of the first two years might be shifted, school bearing part of the responsibility of chemistry and biology and the later years that of advanced anatomy and physiology, and in this way the professional training itself might possibly begin in the second year, whilst from the beginning the faculty of observation would be trained in those fields where it will be engaged in practice. None of you will have the benefit of these changes, but their mention may have provided you with clearer ideas and, perhaps, with some suggestions as to the most profitable way of looking at your studies. It is the study which is preliminary, not the subjects, for anatomy is part of clinical medicine and physiology is its very breath. The distinction between their educational and their utilitarian side is one which no teacher of a special branch would care in fairness to the integrity of his subject to emphasise too strongly but which is essential from your standpoint. Some of the superabundant supply will be retained and will help to educate the clinical man, but the greater part is sure to be lost to conscious memory. Inquire of your fellow-pupils and of your teachers which are those portions of your daily anatomy and physiology which are to form part of your professional outfit and to be kept ready for use. Let your study of visceral anatomy and physiology, and above all of practical urology, hæmology, and glandular physiology be undertaken and carried out with the care and forethought which belong to the safe keeping and to the utilisation of capital. Meanwhile, any premature attempt to take any part in clinical work or to visit the wards is futile and detrimental. But a distant message of advice may harmlessly be sent from them to you whilst you linger in the Eden of science, and it is this: see to it that the precious fruit you are gathering does not run to waste and your scientific weapons do not rust before the time when they will be wanted.

### A NEW SUBJECT: CLINICAL TECHNIQUE.

The ancient and mediæval artists made and mixed their own colours. This was a purely technical operation which might, so far as the successful painting was concerned, have been done at a distance. So it is with many other points in the technique of all arts. Clinical technique, though it is unrecognised in the curriculum, has now grown into a full-sized subject comprising regional anatomy, important parts of practical physiology, of physiological chemistry, of histology, and of bacteriology, in addition to the entire technical detail of physical examination, to medical terminology, and to systematic note-taking. The accessory clinical methods and apparatus are now becoming so numerous that it is difficult in the wards to apply them all even in the service of the patients, much less for the individual teaching of students. This tuition should largely be conducted elsewhere and its proper place is a special laboratory. Nowhere really at home, and everywhere inevitably an intruder, in the dissecting-room, in the chemical, the physical, the physiological and the bacteriological laboratories, and above all in the wards themselves, clinical technique has hitherto led a wandering and parasitic existence. Clinical medicine and its students will not have had their due until all the *disjecta membra* indispensable to their work shall have been consolidated into a working whole and duly housed in a laboratory furnished with all the material, apparatus, and diagrams essential to a thorough and rapid grasp of the entire subject. I believe that the practical study of science and that of clinical medicine have been kept too much separated, and I cannot view without misgiving any prospect such as is now being discussed of rendering that separation absolute in space as well as in time. In my opinion the solution which is sought lies in an opposite direction. The delay which has occurred is but a repetition of previous experiences. Laboratories of research in chemistry and in physiology had existed long before educational laboratories were instituted for the benefit of students of medicine. In the same way the teaching of clinical technique, the only variety of practical science work which is in daily use by the practitioner, will be the last to be duly provided for. My proposal is that the practical subjects which belong to clinical technique be grouped in the curriculum after the preliminary and before the clinical period of training and taught practically in connexion with a clinical laboratory. A fundamental advantage would accrue in respect of the science curriculum. At present much which practically belongs to clinical medicine is taught under the science schedule without any point of contact with its clinical purpose; lost among a mass of less indispensable theoretical knowledge it overloads the memory for a time and is quickly forgotten. This practical matter needs to be taught at the time when it is put into use; or it should be identified with clinical use at the time when it is taught. A practical course on "clinical technique" dealing with "clinical physiology" and "clinical anatomy" would imply neither additions to the schedule nor any change in the educational periods, but only a trifling redistribution in the subjects. The latter, for instance, would still be taught in the second half of the second year; but the students would have passed from the stage of "preliminary" to that of "applied" science, or clinical technique. The indispensable basis of this scheme would be practical tuition and practical work in a clinical laboratory.

In this century, which bids fair to be the century of medicine as the last was the century of surgery, the clinical laboratory is likely to become one of the most important educational levers. A complete clinical laboratory is a combination of the chemical, physical, physiological, bacteriological, and pathological laboratories brought into working relation with the wards. The clinical laboratory of research in the service of pure science and the ward clinical laboratory in the service of practical hospital treatment have already been inaugurated. But there is a third variety still wanting, though not less important—the students' clinical laboratory. Many students still fail to obtain that expert familiarity wi the physical and chemical methods of examination whic to be expected of them. They have been well taught, they have not practised enough for themselves for the wa of systematic opportunities in suitable surroundings. T wards and the out-patient room afford admirable opportunit for the study of morbid physical signs, but these chan are, in my opinion, too casual and precarious for a systema demonstration and rehearsal of the methods themselves. place is needed for the unhampered tuition and practice the methods and apparatus. Whereas anatomy, physiolog chemistry, and pathology all possess their individu sanctum, the most important of all our applied scienc clinical medicine, has no place to call its own. This def may sooner or later be realised, and every school m ultimately possess a students' clinical laboratory, where science student and the clinical worker might meet common ground, the first in the pursuit of his scienti studies, the other because of his clinical reference to scien Without stepping beyond the school precincts or boundaries of his own subjects, the junior student wou learn that his senior from the wards was applying precis those chemical tests and instrumental manipulations whi he himself was learning, and he would take note that th should not be forgotten. A laboratory of this kind, t student's own test-room, under suitable junior tutorshi might with advantage be utilised for the teaching a practice of the professionally useful aspects of physiolo and of physiological chemistry. For instance, the bloo urine, and digestion tests might be taught and practis there, and a practical familiarity with the respiratory a cardiac sounds acquired with the help of a living subject attendance. The theory of the stethoscope itself and percussion might readily be explained, and much oth arly practical training has always been in this country the adition for all careers. The apprenticeship was intended train up the future medical man from the practical side; esides an elementary introduction to medicine and surgery ere was much in it which was to prove of use in the daily utine of the profession—namely, an acquaintance with me of the functions of the apothecary corresponding to ose of our nurses of to-day, and with some of the functions the dispenser which included the handling of drugs and e preparation of remedies as well as their uses. By degrees, lso, the apprentice grew into the ways of practice, developed a sense for those requirements of the patient which re not purely medicinal, and evolved the professional ttributes of tone and manner which are often the most nportant aids to treatment, at any rate for its appreciaion. This was an exclusively clinical training, in itself ational and good, and well suited to the needs and pportunities of the time.

We need not follow the series of changes which have nded in our present system; they corresponded to the eriod of evolution of modern science and to its increasing influence in medicine. Knowledge which could ot be acquired in the country surgeon's practice had o be sought in the medical schools, and gradually he apprenticeship died out, never to be revived in its riginal form, and the loss of its educational functions was ever completely made good. Whilst this blow had been truck at clinical education a powerful stimulus was given to he study of anatomy which contributed to the great levelopment of surgery at the end of the nineteenth century. The second third of the century was witnessing already a urther change: a scientific training had been thought of, nd since then the constant struggle has been to keep nedical education up to scientific date. On the continent he State-aided universities took the lead in practical aboratory training and outstripped us fully for one generaion; but we are now drawing level with them Early ractical training is once more the order of the day, but it is o longer devoted to clinical medicine but to pure science; nd from this change there is no going back. More and nore time had to be claimed for science until at last, before he introduction of the five years' curriculum, clinical medicine and surgery were reduced to starvation allowance. Whilst, then, originally the tendency was simply clinical, now pure science precedes for two years the purely clinical stage. In the future, perhaps, the study of science may go hand in hand with clinical study to the end of the curriculum. More recently other minor revolutions have taken place, such as the sacrifice of the ornament of classical education and of the proud ambition to know *de omni re.* Some useful collateral subjects, such as botany, zoology, and mineralogy, have practically been given up, though they may now be missed by the few in connexion with exploration and by all in connexion with the coming subject of medical climatology.

### THE CURRICULUM.

The present curriculum has been so difficult to arrange and is so perfect in its adjustment that none would dream of touching it so long as it continues to serve. Its provisions, if they entail great labour—sometimes almost to the verge of endurance—at any rate spare the student all loss of time and all perplexity during the hardest struggle, that of the first two years. At the same time it is obvious that there can be no finality in curricula, for whilst the march of science is continuous and gradual, their changes are artificial, spasmodic, and radical, and therefore subject to amendment. Even our present system is not sufficiently elastic to lend itself to future requirements. Modern medical education presents the following features in contrast with previous conditions: (1) the large share awarded to pure science; (2) the increased importance given to practical work in science, (3) the strict exclusion of any clinical subject from the science curriculum; and (4) the practical exclusion of any systematic study of anatomy and of physiology from the later years. There has been an artificial separation between the scientific and the clinical training; and the question is whether this teaching in compartments has been a success in the direction of clinical fitness. It is too often obvious that those fruits of the science course which are essential to clinical efficiency—physiological chemistry and visceral anatomy—are not available when they are wanted, that the burden to the memory has been too great, and that some relief is needed. Both compartments are overcharged—chiefly, perhaps, that of science, owing to its strict limitation to two years. Meanwhile, the claims of clinical medicine are paramount; but whilst this subject has become enormously expanded the time allotted to its study has been relatively reduced. The consequences were to be foreseen. They are the clinical laboratory with its cry for still more science, and the post-graduate system with its cry for still more clinics.

All the remedies proposed are too radical for immediate application. To reduce further the number of subjects is a policy not much in keeping with modern developments, for the more science we get so much the better, so long as it is useful science, whilst clinical training can never be awarded too much time. Again, we cannot contemplate any further extension of the period of study. Five years of professional training is the fourteenth part of a man's life and should be enough for any profession. Therefore, without any prolongation we shall have to provide time for the study of the *new* sciences to come and for their ever-increasing clinical applications. Three indications lie before us: (1) to unload the science curriculum; (2) to make an earlier clinical beginning by introducing a new subject, that of "clinical technique," and a new laboratory—the "clinical laboratory"—as a link between clinical medicine and anatomy and physiology; and (3) to extend higher science training into the later years of the curriculum.

### UNLOADING THE SCIENCE CURRICULUM.

The best means of unloading the curriculum are probably the following: (1) redistribution in the order of the subjects and in the time arrangements; (2) condensation in the teaching; and (3) specialisation in the selection of the subjects; and all three may need to be combined. The most effectual relief would be to transplant some of the subjects either into the period of schooling or into the clinical period.

*Redistribution in the order of the subjects and in the time arrangements.*—Much would be gained if suitable subjects, such as chemistry and biology, could be disposed of prior to the matriculation. The selection of medicine as a career would have to be made at an earlier age with a view to a special course of study during the later years of school education. We have before us the example of the training for the Royal navy Our medical training, also, is sufficiently different from all others to deserve an unusually early beginning, whilst any special preparation received on a mistaken vocation would not in this instance warp the habits or the mind, but would prove to be an admirable foundation for any other career, including even the clerical. Moreover, school specialisation would soon reveal natural aptitudes or their absence, with ample time for any change of line. This "school-science" might prove to be the hitherto unprovided equivalent for a classical education, because of greater value than a course in foreign languages. Any foreign literature likely to be of use to the majority of practitioners is now translated and soon available, and the conversational need practically does not arise in this sea-girt land. Foreign languages are a luxury, but their acquisition should be economical and properly belongs to the dame-school period, or later to the business of a short educational stay abroad. If some such provision could be made for an early science training, largely practical, prior to the matriculation, 18 months might perhaps be sufficient time for a modified and condensed course of anatomy and physiology. And this brings us to the second of the remedies suggested.

*Condensation in the teaching.*—In all the preliminary subjects some of the more theoretical details might be eliminated without serious loss to the general educational purpose. In the case of anatomy and physiology specialisation would be a more correct term, as the modification to which I refer would consist in adapting the teaching more closely to the practical needs of medicine and surgery and in condensing the more theoretical portions. The relief thus obtained might mitigate the prevailing dread lest any clinical impressions should disturb the fine balance of examination fitness in the preliminary subjects. It is, indeed, much to be desired, though hardly possible, that the student might approach the study of his physiology with undergraduate strength and memory but somewhat in the spirit of a post-graduate.

*Specialisation in the selection of the subjects.*—This is also applicable to the later years of study, when increasingly clinical uses are now found for our scientific training; and this rather suggests a shifting of some parts of the science chief pain, discomfort, or disability? Too much value cannot be attached to the diagnostic importance of pain as a safe indication of something wrong, and often of the nature of the disturbance. Your further investigation will be guided by your acquaintance with the disease. Clerking thus becomes a direct incentive to reading, which at once widens your inquiry. You become an observer and you begin to read disease at sight. For this daily visits and examinations are necessary in your acute and rapidly varying cases; but in all cases continuous observations are wanted. In each case there is some clinical incident which works through vicissitudes to a final *dénouement*. *Respice finem.* You must be there at the finish—the point in the clinical record lies in the conclusion.

There are three kinds of clinical notes, each suited to a different purpose. The academical or full report notes are essentially educational. For the purposes of strict clinical study a much shorter style is required; these are the short, practical, clinical notes. Lastly, there is the memorandum note, note-taking reduced to its simplest expression—*multum in parvo.* To report a case fully and in academical style is a lengthy and laborious task, yet indispensable as a training to accuracy and thoroughness. All the facts of the case, including the negative facts, are stated almost as fully as in a legal document. I conceive no more profitable introduction to ward work than a progressive course of clinical histories, one to be taken every day till the necessary facility is acquired. This is one of the most important exercises in clinical technique.

*Advanced clinical notes.*—These are not, like the full reports, almost photographic in their completeness and lack of perspective. There is in them less writing and more point. And yet they tell us more than the other reports, but largely by implication—much of the inquiry being expressed merely in the conclusion arrived at, in direct statements duly tested, and in hard facts. This kind of note can only be expected from those highly trained in clinical and scientific observation who need no longer record each step in the examination, and it is the style of note-taking that can best serve your laborious clinical studies.

*The condensed system of note-taking.*—In carrying this out the official reporting style in two degrees answers best. Rough notes are unwieldy and often unreadable. Abstracted from the pocket-book a condensed note saves much useless writing and big facts are not buried. In short, learn to be searching in the inquiry but selective in the record—observers of many facts but writers of few. For a coming generation shorthand may be one of the conditions of existence. In connexion with clinical medicine it has already been sufficiently advocated. Its inclusion among the subjects for matriculation would be vastly more important than that of any foreign language. Many systems and forms have been suggested for note-taking; intended to save labour they sometimes fail to do so, and on the whole it is better perhaps to have *carte blanche* and to carry out consistently one's own system. The temperature chart, which carries much of the essential information in figures, often serves as a single sheet record in acute cases of short duration when not so complicated as to call for more space. Short methods such as these enable clerks to keep simultaneous reports of several cases, and six months of this kind of work would provide them with experience and records of a good assortment of diseases. Yet further opportunities are given by a denser form of notes, perhaps the only one possible in the hurry of practice—viz., the retrospective or *résumé* note.

*Résumé notes.*—These are not much more than headings descriptive of the striking peculiarities of cases. This form of note will teach you concentration and grasp of a case, and later in practice rapidity of perception and of action irrespective of minute disquisitions which obscure the real issue and often ruin diagnosis. Since one or two copies can be quickly obtained by the perforation method a mutual arrangement would enable each of you to obtain memorandum charts of those cases which have been allotted to your fellow clerks, but which may have been seen and examined by you day by day. This part of your valuable experience would in this way be added to your permanent records and your clerkship would provide you with a considerable series of personally observed cases with their illustrative curves.

### THE STUDENT AND HIS WORK.

*Self-help.*—I should like to be able to offer to you as students a few words of practical advice and encouragement. Pure art, we are all aware, needs special gifts. *Nascitur non fit* is true, not only of the poet, but also true of the physician, who has to be all things to all men and whose knowledge of disease is in vain if he lacks the knowledge of man. Nevertheless, there is probably no profession in which persevering labour so safely brings its reward. Self-denial and hard work are infinitely more essential than great talents. Let us who may be relatively less gifted, then, take comfort in the thought that our privilege is to work, and, working, learn to the end of our days. Success in every line of life belongs to a single-minded attention to the business in hand and to those great economisers of labour, punctuality and a daily settling up of the work of each day.

*Mutual help.*—Much help also comes from combination. Collaboration in study, as, later, consultations over difficult cases, affords a multiplication not only of forces but of their directions. Individual divergences of thought are brought to bear, and even our relative defects may lead to profit if they should elicit greater work from our differently gifted associates. I can picture to myself the draughtsman among you helping the musician with his diagrams and in return receiving his assistance over the mysteries of percussion.

*Self-education.*—The line for special attention is always that of the least aptitude. The easier performances will profit by the effort. But the lame function, if it be neglected, becomes relatively weaker from disuse. Let me name as an instance the most essential of collateral studies—that of drawing. To be unable to draw is to lack the use of a sense which is of primary importance to the medical student. The time, I hope, may soon come when drawing will be regarded as one of the most important subjects in the entrance examination. But it is after all only one of the practical subjects in which the pupil has to practise self-education.

*Technical self-education and the training of the senses.*—Both sets of faculties, the physical and the mental, need to be trained. The examining board looks after your intellects, it is for you to look after your senses. The average student devotes hardly sufficient time to improving his mechanical experience. It is said of Paganini that much of his technique was evolved by his individual efforts; and other great artists have achieved perfection by solitary study. But the study of art is facilitated when, as at the Royal Academy of Music, technique has a local home and habitation, with its teachers and its pupils, its demonstration and its practice, and, above all, the necessary technical appliances, luxuries which the clinical student of the future may likewise enjoy. Meanwhile you are dependent upon your individual industry. Proficiency in auscultation and percussion, as in instrumental music, needs long practice. This is a reason for making an early attempt in this direction. The use of the ophthalmoscope is a physiological recreation which taken early would also be of great advantage, and the same is true of the sphygmograph and of other physiological instruments essential to clinical investigations.

*Taste.*—The exercise of taste is generally restricted to the appreciation of the medicine we order, a practice much to be recommended to prescribers.

*Touch.*—Touch, one of the most helpful of our senses for clinical work, is perpetually under training in early life, but improves by systematic education, as in the cultivation of some of the arts, and by the endeavour to train both hands.

*Hearing.*—The ear has wide scope in the study of auscultation and percussion. Immediate auscultation has its use in some cases. Great importance attaches to the student being taught the use of the simple rigid stethoscope before he is allowed to touch the binaural. This latter is less reliable by reason of its complexity and of its mode of conduction.

*Sight.*—Sight hardly needs specialised cultivation. But it is possible to see and yet fail to perceive. Accuracy in visual judgments and examinations is a matter for constant practice; and I may mention the practical rule essential to diagnosis, that of not standing in your own light but of placing the patient in it.

*Smell.*—Our sense of smell, trained by use rather than by system, is far inferior in critical power to that of the dog, who assiduously practises this sense, although in a different sphere. His speciality is the animal kingdom. Most of us are familiar with the smell of *genus homo* and of most animal tribes; and, as Shakespeare has it, we may even distinguish a nationality:

> "His word was still,—Fie, foh, and fum,
> I smell the blood of a British man."
> —*King Lear*, Act III., sc. iv.

clinical information facilitated by reference to the diagrams and apparatus belonging to the laboratory

With the dissecting room the clinical laboratory would be in close sympathy Medical and surgical anatomy, prominent requirements of the later examinations, would be represented by casts or diagrams, and on doubtful points of visceral anatomy frequent reference would be made to the post-mortem room The existence of a clinical laboratory of this sort would go far to animate with a clinical purpose much of the work of the first two years, and the helplessness of clinical beginnings, imperfectly met by the course of practical medicine, might be more quickly remedied

### The Clinical Curriculum and the Clinical Clerkship

In the clinical curriculum no sweeping change has been made The clerkships which existed 100 years ago have been continued, and beyond the requirement of a minimum period of six months no definite regulations have been imposed from above Meanwhile the spirit of clinical medicine, its needs, and its weapons have altered *toto cælo* But the extent to which the individual student's time has been adapted to the altered requirement has varied much with local traditions and immediate surroundings Some of our schools have wisely relegated the clerkship to the fourth year and enforced a preliminary technical training during the third year At others, less happily, the clerk's attendance sheet may be signed up quite irrespective of his clinical standing Walking the wards whilst always profitable, is, clinically speaking, a passive function Active practical work, of which there is always plenty to be done in collaboration with those in office, is the work which will secure your success at examinations and in practice It should be begun without a day's delay and carried on to the end of your hospital days, but it needs to be systematic

The highest form of practical work is the advanced clinical clerkship—a fact not always recognised by the pupil until he returns to clinical study as a post-graduate The clerkship is the golden time of clinical training which makes the physician Doubtless it furnishes the beginner with material to learn how to use a stethoscope, how to percuss, how to test urine, and how to write out a clinical report But the clinician is not to be made at this rate, unless the clerkship should be continued for double the period Do not throw away your valuable time of clerking upon an elementary mechanical training which should have been acquired previously in the wards and in the laboratory Some confusion seems still to be made between the purposes served by the ancient clerkship and by the modern clerkship respectively

*The ancient clerkship* —The ancient clerkship was analogous to the apprenticeship which it replaced, a school for professional ways and phraseology, for simple observations and theories rather than chemical and instrumental investigations For this no time could be too early and the student was made to plunge *in medias res* without any further preparation

*The modern clerkship* —The modern clerkship is totally different I see in it an official appointment of dignity and importance with valuable prerogatives which come next to those of a junior officer The clerkship is for most students the only direct apprenticeship to actual charge of patients except the brief period of obstetric experience which falls to the lot of all This ought to be if it is not in every case, the practical value of the appointment to the clerk The clerk's official privilege is that of daily examinations and inquiry, which alone teach him to judge at a glance of the patient's progress His professional experience grows at a rapid rate, in proportion as he is capable of independent action Much of all this is lost to the unequipped tyro He ripens for his office just when it is time to retire

*The junior and the senior clerkships* —The essential difference between the elementary and the advanced or finishing period of ward work might be identified with two grades of office, a junior clerkship under the house physician or the medical tutor, and a senior clerkship under the physician The first of these could hardly be held too early, the latter could hardly be taken too late The whole interval between them would then become for the fully equipped student one of clinical profit whether from book work, from lectures, or from walking the wards Much of the junior clerk's time would be spent in the out patient room and in the wards, where he would take systematic daily notes of easy cases offering good opportunities for the physical examination of normal organs and for practising instrumental methods such as the sphygmograph the cardiograph, and others Much time also would be spent in the laboratory, in microscopical examinations, and in chemical testing Lastly, as a finishing touch to his professional training would come the senior clerkship with its wealth of opportunities limited only by the relative fitness of the worker In terms of art these periods correspond to two studies—that of technique and that of production Your work of art is to be the investigation of disease and its treatment, and your studio is the ward during the period of clinical clerkship But success in the performance cannot be attained without a preliminary technical preparation, although, much to your detriment, the regulations admit of your making the attempt

*Examination in clinical technique* —The educational authorities have chiefly laboured at introducing and elaborating the modern scientific curriculum; clinical education, which had always existed, has been left to take care of itself, but it needs to be more thoroughly organised The all important subject of clinical technique has never received any separate official recognition either in schedule or in examination Not a lover of examinations, I regard a technical clinical examination to be held some time in the third year as a necessary and a merciful evil, since, unlike others it would not merely test the ephemeral possession of a limited number of established facts but the lasting command of an unlimited supply of personal observations Its scope would be sufficiently large without implying the slightest addition to that which is already taught, since it would embrace the use of physiological instruments applicable to clinical study, and of purely clinical instruments the elements of physiological chemistry, visceral anatomy, including surface markings, the technicalities of medical terminology, and, last but not least, the systematic note taking to which I shall presently refer The best mode of qualifying for this practical examination would be practical work in a clinical laboratory such as I shall proceed to describe

Gentlemen beginning your third year, the practical point which arises out of this survey is that you should anticipate by your combined efforts some of the advantages which may not be yet offered to you Practise your clinical technique among yourselves by twos and by threes, and for this the best place of meeting is not the ward, but wherever you find the necessary freedom and quiet. Discuss your clinical subjects just as you have met and discussed your anatomy For the present your clinical laboratory work must be peripatetic, and doubtless you will be welcome to use in succession for your private study the various science laboratories of your school

Gentlemen in your second year, help each other with the acquisition of knowledge and test each other as to its clearness and retention Set still greater value upon your practical work in connexion with its clinical purpose Bear in mind the professional uses of trained experimentation, of dexterity in manipulation, and of most of your physiological tests Allow nothing of your knowledge of the functions and of the secretions to slip Then, as to the early familiarity with auscultation and percussion, failing a *corpus vile* to practise upon in a clinical laboratory you have the willing offices of each other to investigate the practical physiology of respiration and of the heart's action with the stethoscope, of the pulse with the sphygmograph, and of the visceral anatomy by rough percussion , and you will always find a willing senior pupil to help you with your first attempts or with any needful explanation In my belief these useful pastimes are not likely to detract from your devotion to your set subjects or to endanger your examinations, but, on the contrary, would add meaning and zest to your studies.

### Clinical Notes and their Varieties.

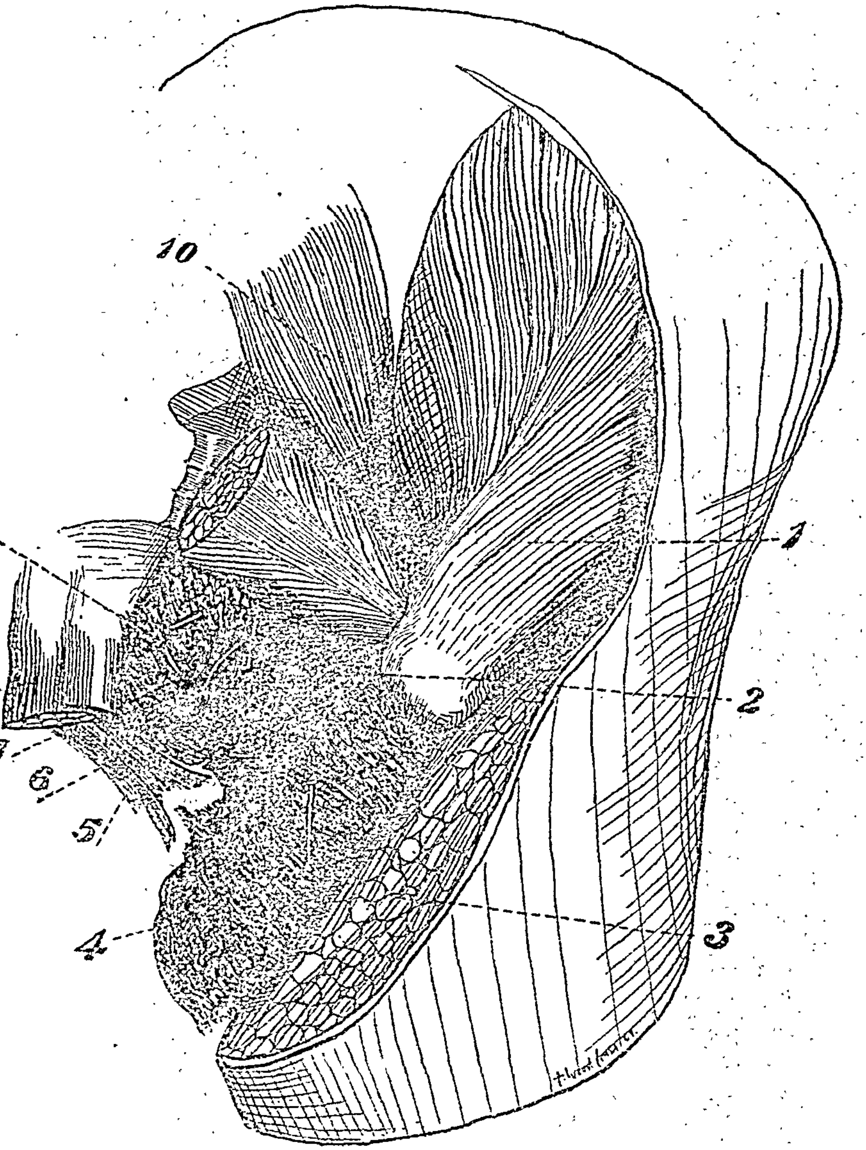
In note taking there are two departments—the recording of your own observations which are systematic, and that of the patient's statements which are often a mass of confusion To meet this difficulty let your inquiry be so far as possible quantitative—e g , as to dates frequencies, amounts, &c Figures are most convenient if trustworthy, and they show up at once any contradictory statements. The patient as he appears before you often carries his diagnosis written large in his aspect , but if this should not suffice as a guide two simple questions help to identify the condition as acute or chronic (1) How long has the patient been in bed or incapacitated ? , and (2) In what part of the body is the

# CASE OF RECENT TRAUMATIC PERINEAL DISLOCATION OF THE RIGHT HIP WITH A DISSECTION OF THE JOINT.

BY HUGH M. RIGBY, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO POPLAR HOSPITAL.

DURING May, 1901, two cases of dislocation of the right hip were admitted to the Poplar Hospital. The first was under the care of my colleague, Mr. A. B. Roxburgh. Both were cases of perineal dislocation of the right hip-joint, both were in young, powerful men, and both presented practically the same physical signs and symptoms. In the first case (Mr. Roxburgh's) reduction of the dislocation was easy and recovery was uneventful; in my case, unfortunately, death suddenly took place a few minutes after an easy reduction under anæsthesia. The following are the notes of my case. The drawings, made by Mr. Wood Jones of the London Hospital, show the condition of the joint 24 hours after death.

FIG. 1.



View of the dissection from behind. 1, Gluteus medius. 2, Obturator externus (torn). 3, Gluteus maximus. 4, Quadratus femoris (torn). 5, Obturator externus (torn). 6, Head of femur. 7, Edge of acetabulum. 8, Origin of hamstrings. 9, Quadratus femoris (torn). 10, Pyriformis.

A man, aged 23 years, was working in the hold of a ship in the docks. He was engaged in hoisting up bales of wool. For some reason the claws which grasp each side of the bale became unhitched. One of them struck the deceased on the left side of the face and simultaneously the bale of wool fell on the right thigh. It was impossible to find out how the deceased was actually standing at the time of the accident, but apparently the bale struck the right femur on its antero-external aspect, somewhere about the middle of the shaft. On admission to hospital there were an abrasion on the left cheek and two small wounds on the left side of the forehead. The right leg was flexed, abducted, and slightly rotated outwards. The amount of flexion was roughly an angle of about 30° with the horizontal and the amount of abduction was about 40° with the sagittal plane. The leg was kept firmly fixed in this position and any attempts at movement, either active or passive, caused much pain. There was lengthening to the extent of one inch on the affected side by spino-malleolar measurement. The great trochanter was buried and there were distinct flattening and broadening of the right buttock. A swelling which proved to be the head of the femur could be made out in the perineum. The adductors were tense and prominent, as was also the lower part of the gluteal mass. The patient was a man of very powerful build, the glutei and all the thigh muscles being exceptionally well developed. A diagnosis of perineal dislocation of the hip was made and reduction was proceeded with. Chloroform was administered. The right leg

But the dog can tell us not only the species but the individual. The almost inconceivable efficiency to which this gift is educated is the result of constant study. The canine mind and memory must be largely aromatic or made up of fragrancies We humans are on a much lower platform, but such as they are our powers should be utilised, for diagnosis sometimes depends upon their exercise. To say nothing of epiphytic and epizoic odours, such as those of favus, phtheiriasis, &c., typhus and small-pox and some other diseases can be identified by the smell of the patient. The smells characteristic of phthisis, rheumatic fever, &c., are probably a mixed product, due less to the micro-organisms than to the excretions. Bad smells are becoming scarce, particularly in hospitals, but greater importance attaches to the examination of (1) the secretions and of (2) the patients, and this duty must be faced where patients' lives are at stake.

*The secretions.*—An inspection of the fæces is not neglected by physicians, but other secretions are more accessible to students. The urine, which may smell of diabetes, of alkaline or acid decomposition and other fermentations and of various ingesta, is usually reserved for our examination. The smell of the vomit, a guide to the detection of volatile poisons and ingesta, such as alcohol, may also be the means of identifying the seat of disease Life and death have often turned upon the question whether the smell of the vomit was stercoraceous. The examination of the sputum is also of daily and practical importance. Here, again, the difficulty is to procure it in its original septic state.

*The patient.*—As regards the patient, the most essential of our olfactory examinations of patients concern the nose, the mouth, and the ears. Most vital conclusions are sometimes based upon the septic smell detected in the ears of infants and young children; and the neglect of this examination may cost the child's life. A heavy, foul breath seldom escapes recognition, but we should in every case localise its origin by examining the patient's breath alternately whilst the mouth or the nose are closed. Often the smell is from the nose, as in ozæna and dry fœtid catarrh; and unless recognised this may escape its proper treatment. The mouth is the most fertile source of distinctive smells, such as the respiratory effluvia in bronchiectasis or gangrene and other conditions, but most of the bad odours are of local production Foremost as frequent causes of disease are dental caries and degeneration, as well as the fœtid conditions of the gum found in hæmorrhagic stomatitis, in pyorrhœa, and in gangrene. Follicular fœtid tonsillitis and various conditions of the retro-nasal fossæ have also to be accounted for. Putting all this aside, the breath is of vital diagnostic importance in diabetes and in uræmia, and patients with chronic disease should always be examined in that direction.

In conclusion, the subject of this address has hardly received full justice at my hands or much literary ornament I came to you less prepared for an academical function than to talk as a student to students, to suggest some of those special hints which veterans often have to offer, and to discuss with you with the advantage of some slight experience your plan of campaign. May I have been *so fortunate as to adapt my remarks to my audience and to* their practical aims and to have in some measure fulfilled my intention to direct their whole-hearted attention to the every-day trivialities of clinical study and their thoughts sometimes also to the higher ideals of the art

# A FURTHER NOTE CONCERNING THE FRONTAL OR SUPRA-ORBITAL REFLEX.

BY WALKER OVEREND, M.A., M.D. OXON.,

LATE SENIOR PHYSICIAN TO THE TOTTENHAM HOSPITAL.

REFERENCE was made in an annotation in THE LANCET last year[1] to the facial or supra-orbital reflex and a summary was given of the recent researches of two observers—McCarthy and Hudsvernig. I cannot refer to the *Neurologisches Centralblatt* for a full account of their work, but I may state that I first described this reflex in 1896[2] under the name of "frontal" and demonstrated it to medical friends as far back as in 1889. In this communication I indicated the reflexogenous area and came to the conclusion that it was a true skin reflex inasmuch as mere stroking of the skin is sufficient to evoke a response when the latter is in a condition of hyperæsthesia McCarthy's statement that division of the supra-orbital nerve abolishes the signal corroborates this view. Further observation, however, has taught me that it is not only the supra-orbital but also the cutaneous and periosteal terminal twigs of the supra-trochlear, infra-trochlear, nasal, and lacrymal, in fact, *all* the end branches of the ophthalmic nerve, which are concerned. In other words, tapping of the nose (nasal) with the eyelids closed, of the inner surface of the nose and the eyebrow near the inner canthus (supra- and infra-trochlear), and of the external angular process of the frontal bone (lacrymal) is able to produce the movement. The terms "supra-orbital" and "frontal" as applied to the reflex are, therefore, inappropriate. Moreover, the term "facial" is still less accurate, since there are *several* reflexes (as the corneal and the lacrymal) which occur in connexion with the facial nerve and the face. There is one reflex in this region which has apparently escaped description—namely, an *aural* reflex which may be induced occasionally by stroking gently and quickly downwards the skin (supplied by the auriculo-temporal nerve) in front of the ear in young infants. After a little patience and perseverance the ear may be suddenly elevated—a result due to contraction of the attollens aurem which is supplied by the small occipital nerve It seems to be a true skin reflex and identical with that which is more easily obtained in some of the lower mammalia. This reflex, moreover, obviously belongs to the area of the face.[3] The term "facial" is consequently unsuitable and I propose that of "ophthalmic" as being more in accordance with its distribution.

In my former paper I expressed the conviction that the sign was not due to the communication of physical vibrations, since the area was most definite. Hudsvernig, however, proposes the cumbersome view that "it is an overflow of the muscular irritability to mechanical irritation into neighbouring muscles innervated by the same nerve," and is led to the theory because he has found that the contraction may be obtained on both sides after the right Gasserian ganglion has been removed I have no opportunity of testing his statement, but before accepting his explanation the exact conditions and relations under which the signal is provoked must be carefully and thoroughly investigated. Moreover, granting the fact, another explanation is feasible. If the cornea near the external canthus of the *right* eye be gently touched or the eye-lashes pulled a twitch in a certain part of the lower *left* eyelid may be observed to accompany the movement in the right eye Furthermore, a contraction of the same strand of fibres in the left eyelid may be subsequently and immediately provoked by tapping the right external angular process It is difficult to conceive how the overflow could leap the bridge of the nose and make itself felt just in the same muscular fibres on the opposite side As ordinarily demonstrated by a tap of the finger with the eyelids gently closed, I believe it is a periosteal reflex induced from the pericranium and periosteum supplied by the terminal twigs of the ophthalmic nerve, with a reflex centre corresponding to that of the corneal reflex in the medulla. I drew attention to the fact that in chorea and supra-orbital neuralgia the movement may be produced by tapping the head as far back as the parietal eminence A similar distribution is often seen in hysteria. The reflex is absent in chloroform narcosis and in facial paralysis I have found it difficult to obtain in paralysis agitans In a patient with hemiplegia and hemianæsthesia it was absent on the paralysed side for several days after the attack, but when the skin of the normal half of the forehead was tapped *both* orbiculares could easily be made to respond.

My object in writing this note is to call attention to the more exact designation "ophthalmic" and to emphasise the view that the signal is a true reflex and obtainable from both the skin and the periosteum supplied by that nerve.

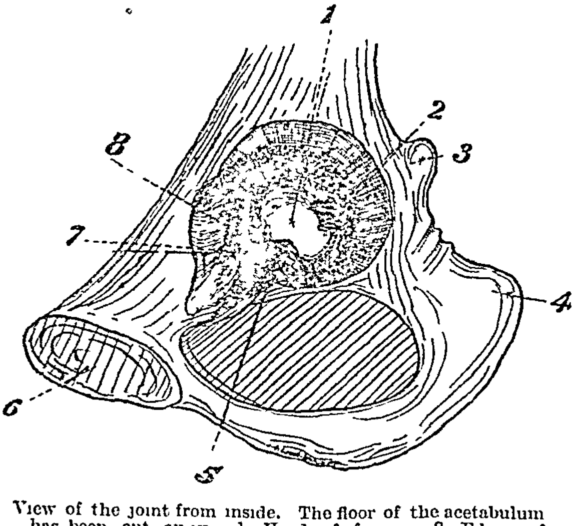
BRISTOL MEDICAL CHARITIES.—During 1901 the employés of Messrs. J. S. Fry and Sons collected £565 for the various Bristol medical charities.

femoris was torn right across as if cut with a knife, except for a few fibres at its lower edge (4 in Fig. 1). On separating the torn fibres of these two muscles a view of the back of the capsule was obtained. The back of the head and neck of the femur and the posterior surface of the acetabulum were exposed through a window torn in the capsule at the bottom of the cavity. The torn edge of the capsule was seen at the upper and outer part, extending from the acetabular margin to the upper end of the digital fossa. Beneath this free margin some fibres of the external obturator muscle had been caught, probably during the reduction of the dislocation; the cotyloid ligament and the edge of the acetabulum were apparently intact. The retinacula of the capsule were seen on the posterior surface of the neck; three or four of these had been stripped off the bone. 2. Dissection from in front (Fig. 2) The sartorius muscle was entire, as was also the rectus femoris; these two muscles were next cut through and turned up. Much extravasation of blood was apparent between the insertion of the rectus, vastus externus, hamstrings, and outer surface of the iliacus muscle. The upper fibres of the vastus externus were seen to be torn through at their attachment to the front of the base of the great trochanter as low down as the level of a line drawn transversely through the small trochanter. The adductor longus was found to be intact. Between the psoas and adductor brevis there was extravasation of blood, probably from small branches of the internal circumflex artery and vein. The fibres of the psoas, pectineus, and adductor brevis muscles were untorn; some bruising was found on the under surface of the pectineus. The psoas and iliacus were reflected upwards to display the ilio-femoral ligament; this was quite entire. The adductor brevis was next divided so as to expose the obturator externus from the front (6 in Fig. 2). Its upper part was found to be intact and the two divisions of the obturator nerve had escaped injury. The lower and inner part of the muscle over the region of the cotyloid notch was torn through and a hole with ragged edges of about the size of a halfpenny became apparent. This was evidently caused by the escape of the head of the femur during dislocation. As before mentioned, the capsule was torn completely through and stripped from the acetabular edge at the lower and inner part, the bare surface extending over the posterior part of the joint. The transverse ligament could be seen intact on the outer aspect, as also could the cotyloid ligament. 3. Dissection from the pelvic side (Fig. 3). This was made to show the ligamentum teres *in situ*. A piece of bone was trephined from the wall of the pelvis corresponding to the centre of the acetabular cup. The pin of the trephine was placed above and to the outer side of the ischial spine, so that the cotyloid notch and ligamentum teres might be displayed. The latter structure was found torn through and hanging freely in the joint A portion of the deep surface of the cotyloid ligament was also found turned into the joint. On turning this back and manipulating the femur the depression on the head was easily seen with some torn fibres of the ligamentum teres attached. The acetabulum itself was apparently uninjured.

FIG. 3.



View of the joint from inside. The floor of the acetabulum has been cut away. 1, Head of femur. 2, Fibres of obturator externus. 3, Spine of ischium. 4, Tuber ischii. 5, Ligamentum teres (torn). 6, Symphysis pubis. 7, Depression for ligamentum teres. 8, Cotyloid ligament.

*Remarks* —There can be little doubt that this case was one of those rarer forms of dislocation of the hip known as "perineal"—i.e., an exaggerated form of the infrapubic variety of forward dislocations. The head of the femur in these cases passes primarily downwards over the cotyloid notch, then downwards, inwards, and backwards on to the ascending ramus of the ischium. The almost unique opportunity afforded for examining the injured structures in this dislocation is my excuse for publishing the case. Only eight cases were found in the literature by Riedinger (quoted in Tillmanns' "Principles of Surgery"). I have been unable to find any published case of dissection of a recent dislocation of this variety, and there is no specimen of its kind in any of the London museums. Several cases of recent dorsal dislocation of the hip have been dissected and recorded from time to time, associated injuries having, as a rule, caused the death of the patient. It is instructive to note the exact condition and position of the damaged structures about the joint and to realise the amount of repair which must take place during the subsequent period of recovery.

The correctness of the diagnosis of perineal dislocation was quite borne out by the subsequent dissection of the joint. A radiograph clearly showed that the head of the femur lay in the infrapubic position. The extreme flexion and abduction and the presence of the head in the perineum all supported this diagnosis. The lengthening—viz., one inch—found by measurement is of doubtful value, as the difficulty of exactly measuring the limb in this position is apparent. As to whether true lengthening or shortening takes place in infrapubic dislocations authorities are found to differ. One would rather have expected to find some shortening in the perineal variety.

The dissections of any recent forms of forward dislocation of the hip have been remarkably few. In the *Medical Times and Gazette*, 1853, Mr. Curling[1] reported a case, as also did Professor T. Annandale in the *British Medical Journal* in 1870.[2] Both of these were thyroid dislocations. It is interesting to compare the injuries found in these two cases with mine.

Mr. Curling's case: "Blood was found extravasated between the muscles on the outer and posterior aspects of the joint and in the cellular tissue about the sheath of the sciatic nerve. The substance of the upper part of the adductor magnus and lower border of the obturator externus were much ecchymosed. There was a large rent in the front part of the capsular ligament, extending from the ilio-pectineal eminence to the upper border of the obturator externus. The ligamentum teres was torn."

Professor Annandale's case: "The obturator internus[3] was torn and portions of the muscle forced into the acetabulum, the capsular ligament was extensively torn on its inner and lower aspects, the anterior and greater part of the posterior portion of the capsule was intact. The Y ligament was also intact"

On comparing my dissection with these two cases one is immediately struck by the difference in the amount of destruction to the structures on the posterior aspect of the joint. Most text-books will be found to agree in their descriptions of thyroid and obturator dislocations with these two recorded cases. All are agreed that the capsule is torn at its lower and inner part and that the ligamentum teres is torn; also, that in all so-called "regular" dislocations the Y ligament of Bigelow remains intact. The obturator externus and in some cases the adductor muscles, are torn to a varying extent. Professor M. Gunn (quoted in Hamilton's "Text book on Fractures and Dislocations") states that in thyroid dislocations the superior and posterior parts of the capsule are intact and relaxed, whilst the anterior and inner parts are usually torn. Mr. Timothy Holmes,[4] in a clinical lecture in 1877, states that the pectineus adductor longus and brevis may be torn and the obturator nerve may be stretched; he however, admitted that the paucity of dissections necessarily weakened these statements.

The mechanism of obturator infrapubic and perineal dislocations is now recognised to be as follows. Usually was then well flexed on the trunk, adducted, and rotated in, very little force being used The head of the femur immediately slipped into the position of a dorsal dislocation The leg was next abducted rotated out, and extended Reduction followed without any difficulty A long Liston splint was being fixed on the limb when the patient suddenly stopped breathing and although every available means of resuscitation were tried they proved ineffectual

[4] Medical Times and Gazette, 1877, Lecture on Obturator Dislocation.

At the post mortem examination nothing was found to account for death, all the organs were healthy and no signs of embolism were found anywhere On superficial inspection of the right hip there was nothing to indicate that a recent dislocation had occurred—no bruising or undue swelling about the joint The following were the conditions seen on dissecting the joint. 1 From behind (see Fig 1) On reflecting the gluteus maximus which was intact and turning back the fascia on its deep surface a large extravasation of blood was found This extended from one and a half inches above the upper border of the ischial tuberosity to just below the lower border of the gluteus maximus The walls of the bursa situated over the great trochanter were infiltrated with blood The great sciatic nerve was divided high up, the external popliteal passing through the fibres of the pyriformis The nerves lay on the posterior wall of a cavity containing blood and bruised and torn tissue The nerves themselves were not torn although deeply stained with blood The sciatic artery and its main branches were intact but the veins and those accompanying the arteries forming the crucial and digital anastomoses were extensively torn The gluteus medius and pyriformis were intact The gemellus superior and obturator internus showed no injury, but the gemellus inferior, though untorn was stretched and bruised, especially on its anterior surface The obturator externus and quadratus femoris muscles were un- damaged The tendon of the obturator externus was split the lower fibres remaining intact but the upper were torn in two and the fleshy fibres partly turned within the acetabulum and caught between the edge of the torn capsule and the neck of the femur The quadratus

The temperature was normal or subnormal during the last two weeks of life.

*Necropsy.*—At the post-mortem examination rigor mortis was present. A little blood was exuding from the nose. The trachea contained frothy blood. A little blood-stained fluid was present in the left pleural cavity. The left lung weighed 16½ ounces; a large infarct filled up about one-eighth of the lower lobe and the blood-vessel immediately above this contained an ante-mortem clot. Many smaller infarcts were also present in this lobe. The right lung weighed nine ounces; there were many pleuritic adhesions and many small infarcts were present in the lower lobe. The pericardial cavity contained about an ounce of clear serum. The heart weighed 11 ounces and was very firm and globular; the right side was much hypertrophied. The pulmonary valves were much thickened and puckered. On two of the valves were large warty vegetations with apparent loss of substance. The right ventricle was dilated, its walls being much hypertrophied, and the musculi papillares were much enlarged. All the other valves were normal. The liver weighed 31 ounces and showed commencing "nutmeg" change, the spleen weighed six and a half ounces, and the kidney six ounces. No infarcts were found in any of these organs. The stomach contained nearly two pints of frothy blood. Blood was present in the duodenum. No ulceration of the mucous membrane was found.

*Remarks.*—The case presented all the classical signs of the lesion. The cardiac apex was displaced downwards and outwards. There were marked dilatation and hypertrophy of the right ventricle and epigastric pulsation. In addition, there was a diastolic bruit heard in the third and fourth left intercostal spaces, close so the sternum, a bruit which might easily have been ascribed to aortic regurgitation, but the typical water-hammer pulse of the latter lesion was absent. Further, the murmur was intensified on expiration and in the upright posture. Emboli were carried to the lungs and produced frequent attacks of hæmoptysis. Such hæmoptysis is said to be present in one-third of the cases, chiefly in those due to infective endocarditis. A capillary pulse has been described as occurring in the pulmonary circulation—i.e., a jerky vesicular murmur, waxing and waning with the cardiac contractions. It was not detected in this case.

It is a curious fact that although pulmonary stenosis is a common lesion it is rarely associated with incompetence, whereas the reverse holds good in aortic lesions. This can be accounted for by the low blood-pressure in the pulmonary circulation not creating a regurgitant stream sufficiently powerful to produce a murmur, even if the valves are incompetent.

The case presented many difficulties from a clinical point of view. The physical signs were those of pulmonary regurgitation, associated with a high complexion suggestive of some pulmonary stenosis, and a variable pyrexia which might be due to rheumatism, infective endocarditis, or pulmonary complications. On the other hand, there was no evidence of pulmonary stenosis, such as clubbing of the extremities and a systolic murmur or thrill in the pulmonary area. The rarity of pulmonary regurgitation made one think that a more probable diagnosis was that of aortic regurgitation, but the absence of a characteristic pulse, the absence of signs of hypertrophy and dilatation of the left ventricle, and the presence of signs of dilatation and hypertrophy of the right ventricle were opposed to such a view. In addition, it would have been necessary to assume the presence of some congenital lesion to account for the high colour. Again, the history of past rheumatic fever and the presence of pain in the knee suggested that the aortic lesion was the more probable, for rheumatic endocarditis rarely affects the pulmonary valves. In fact, in cases of pulmonary regurgitation a past history of rheumatism has only been recorded in about 10 per cent.

Another possible diagnosis was that of mitral stenosis associated with adherent pericardium. In favour of this was a note when the child was first admitted in May that the sounds "seemed a little sticky." The murmur was, however, too characteristic of regurgitation through the aortic or pulmonary valves, and the characters of the pulse were opposed to such a diagnosis.

Infective endocarditis was suggested as a cause on account of the pyrexia and the unusual physical signs. Moreover, it is stated in text-books that a diastolic pulmonary murmur is not heard except in the presence of infective endocarditis. On the other hand, it must be pointed out that the murmur was present for many months and while the patient was apparently in good health. The pyrexia was not serious or constant and there was no fever at all during the last fortnight. The purpuric spots were a little in favour of infective endocarditis, but they were few and soon disappeared. There were no albuminuria, no diarrhœa, and no splenic enlargement. The hæmorrhage presented difficulties; it was, no doubt, from the lungs, but it was always accompanied by vomiting and ascribed by the house physician who saw it to hæmatemesis. If it had come from the stomach it could be explained as the result of cardiac failure and secondary passive congestion of the stomach.

Was the case one of infective endocarditis? On the one hand, this is the usual cause of the condition. On the other hand, the diastolic bruit was present for at least five months before the fatal issue, and the infarcts in the lungs showed no signs of breaking down. Possibly the endocarditis was rheumatic in origin.

Upper Brook-street, W.

# COMBINED FŒTAL AND MATERNAL DROPSY.

By H. VALDEMAR MUNSTER, M.D. Edin.

An example of the above rare condition having occurred in my private practice I have thought the case to be deserving of a place in medical records.

The patient, a married woman, 31 years of age, was due to be confined on Nov. 26th, 1901. I was called to her on Oct. 8th on account of her size being remarkable and her feet being very swollen. I found enormous anasarca of the lower limbs and the abdomen, and my first thought was that the case was one of hydramnios with secondary pressure symptoms, for the abdomen was really enormous, measuring 40 inches in circumference. Indeed, the patient had great difficulty in getting about at all, although she was a strong woman otherwise. On being questioned she said that she had not observed fœtal movements for some time. The urine was very scanty, was loaded with urates, and contained a quantity of albumin. I advised rest in bed. On the 9th I examined the patient more carefully, and found both lumbar regions resonant. The fœtal heart sounds were audible in the usual area and they numbered about 132 per minute. Diarrhœa had occurred several times in the night. My partner, Dr. T. E. Purdom, saw the patient with me on the 10th, and agreed with me in treatment—namely, in advising to await developments. He also thought that the case was one of hydramnios. I was sent for at 5.30 A.M. on the 12th, labour having set in. I found the os dilated, so at 6.30 I burst the membranes when to my surprise only about half a pint of liquor amnii was discharged. I was still more puzzled to feel high up a boggy mass presenting, giving exactly the sensation of pressing an œdematous area. The bowels had been moved at 2 A.M., and urine had been voided subsequently. At 9.15 A.M. I put on forceps and after great difficulty delivered the head of the child, which at first sight looked like an anencephalic fœtus without any bridge to its nose. Subsequent examination, however, proved that the altered shape was entirely due to anasarca. Soon after this the uterine contractions came on with redoubled vigour, but no further progress towards delivery was made although I applied vigorous traction. At 10.30 A.M. I concluded that there was some enormous abdominal tumour in the fœtus rendering delivery by natural efforts impossible. I therefore sent an urgent message to Dr. Purdom, fearing that even abdominal section might be needed to save the life of the mother. Dr. Purdom arrived almost immediately and we at once proceeded to put the patient deeply under chloroform. When she was fully under Dr. Purdom introduced his hand into the uterus and made vigorous traction, the internal hand being hooked between the child's legs and the external hand applied to the child's head and arms, the child being by this time dead. After about 40 minutes' hard work, during which I aided Dr. Purdom by grasping the uterus externally, he succeeded in extracting the body of an enormously dropsical fœtus. The uterus was still quite as big as an ordinary full-term uterus, and the reason of this was found to be that the placenta was œdematous and about as large as four or five ordinary placentæ put together. There was free but not excessive bleeding during the third stage and the liquor amnii was quite of an ordinary quantity.

the thigh is abducted and extended, a force is then applied to the femur directly from the antero-external aspect or to the back whilst the leg is in this position—e.g., in stooping with the legs abducted. The force will tend to hyper-abduct the limb on the pelvis and so to drive the head of the femur downwards and inwards, through or over the margin of the acetabulum into the cotyloid notch. Some authorities believe that this is brought about by direct thrust, others that the *outer* edge of the acetabulum becomes opposed to the great trochanter and so forms a fulcrum of a lever, the long arm being the shaft of the femur and the short the neck and head. In my case probably the question of lever and fulcrum came chiefly into play, as the transverse ligament and edge of the acetabulum showed no signs of injury. The subsequent position of the femoral head will depend on the line of the continuing force. In this case, as we have seen, a heavy bale fell on the abducted thigh on its antero-external aspect; the head of the femur was thus forced out through the lower and inner part of the capsule and eventually came to the fore part of the perineum. With regard to the muscles torn, the obturator externus will naturally suffer most damage as it lies in close contact with the inferior and posterior surface of the neck of the femur. The quadratus femoris is generally torn in pure dorsal dislocations; in this case the complete division of this muscle is interesting

The cause of the untoward death of my patient was obscure and the post-mortem examination threw no light on the matter; the question of anæsthesia may be discounted, as the effects had nearly passed off, the reflexes had returned, and all manipulations likely to cause shock were finished with. A similar calamity occurred under Professor Stokes of Dublin (Stimson's "Text-book of Fractures and Dislocations"). In this patient death was supposed to be due to fat embolism. It is of interest to note that the patient in the similar case preceding mine (Mr. Roxburgh's) made an uneventful recovery; he can walk with very little stiffness and flexion of the hip is nearly normal. He was also a man of powerful build, showed exactly the same physical signs of luxation, and the injuries surrounding the joint were probably similar to those found in my case.

I have to thank Dr. Clement White, my house surgeon, for notes of the case, also Mr. Jones for the drawings, and Mr. Harnack for the radiograph.

New Cavendish-street, W.

# A CASE OF PULMONARY REGURGITATION.[1]

BY EDMUND CAUTLEY, M.D. CANTAB, &C.,
PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN; ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL.

INCOMPETENCE of the pulmonary valves, leading to regurgitation, is rightly regarded as one of the rarest forms of valvular lesions. It is usually associated with endocarditis of the infective variety or with pulmonary stenosis. In an article on the subject by Hale White in Allbutt's "System of Medicine" the writer refers to 99 cases, verified post mortem. More than half of these were due to infective endocarditis. The chief other causes enumerated are pulmonary stenosis, abnormalities of the pulmonary valves, dilatation of the pulmonary artery, and pressure of an aortic aneurysm on the pulmonary valves. Of the 57 cases associated with infective endocarditis no obvious cause was found in 19, but in eight instances there was congenital pulmonary stenosis. As regards age, only two of these 57 cases were in children under 10 years of age, and 12 in patients between 10 and 20 years of age. The present case is an illustration of pulmonary regurgitation in a girl, aged 15 years, secondary to pulmonary stenosis, and associated with acute endocarditis of the valves.

A girl, aged 15 years, was admitted into the Metropolitan Hospital under my colleague, Dr Oswald Browne, on May 7th, 1901, and was discharged on May 23rd. She subsequently attended my out-patient clinic and was re-admitted to the hospital under my care on August 13th, and died on Oct. 10th, 1901. As regards family history it was stated that her parents and two brothers were alive and healthy. She had lost several brothers and sisters, but none had died from rheumatic fever. Two years previously she was in the London Hospital for rheumatic fever. After this she had diphtheria and was in the fever hospital at Homerton. She had been subject to joint pains and she had worked as a feather curler. On May 7th she was admitted for headache, vomiting, and general debility, with a temperature of 103·4°F. The patient had a high colour and was well nourished; there was no clubbing of the extremities or œdema. The apex of the heart could not be localised and there was no thrill. Dulness extended to the middle of the sternum, to the third left intercostal space, to the left anterior axillary line, and down to the seventh rib. The sounds at the aortic base were clear and ringing. At the pulmonary base the first sound was clear, while following the second was a diastolic murmur conducted downwards and heard in the third and fourth left intercostal spaces close to the sternum, being loudest lower down A systolic murmur was also heard at the apex, in the axilla and faintly behind. The pulse was 96, regular, not sudden, of fair volume, and good tension. A few moist sounds were heard at the base of the left lung. No enlargement of the liver was detected. The urine was normal. The temperature fell steadily to normal in two days. In a week she was allowed up, and on May 23rd she was sent to a convalescent home.

The patient remained in her usual health until August 13th when she complained of pain in the right knee and minute bright red spots on the legs. On coming to the hospital in the afternoon she seemed to be very ill and was admitted. Her colour was high, with a slight tendency to duskiness of the cheeks The temperature was 101·6° and the pulse was 108, regular, and of good volume. The lungs were normal except for a few crepitations at the bases. The apex of the heart was in the sixth space in the nipple line; the impulse was not heaving. Diffused pulsation extended for from two to three inches to the right of the sternum. There was marked epigastric pulsation. There was no thrill anywhere The first sound at the apex was rather rumbling in character. Both sounds at the base in the second right and left intercostal spaces were clear and ringing. In the third and fourth left intercostal spaces near the sternum was a diastolic murmur, increased in intensity on expiration and in the upright posture. After being a few hours in bed the pulse-rate fell to 84; in character the pulse was small, soft, and not sudden. There was no evidence of enlargement of the liver and spleen. No clubbing of the extremities was present. On light diet and small doses of salicylate of soda the pain in the knee disappeared in two days and the pyrexia subsided in four days. On August 16th moist sounds were abundant at both bases behind. There was no cough. On the 20th the diastolic murmur was louder and was heard at the base and down both sides of the sternum. The pulse was small and rather sudden. On the 24th there was pain in the right side on breathing which was probably pleuritic, though no definite friction was heard. For the next week she had a moderate amount of fever in the evenings. On the 26th the temperature rose to 103·4°. Nothing was found to account for the fever except the crepitations at the bases. In other respects she felt well. Up to Sept. 5th for a week she had been practically free from fever That morning she brought up three or four pints of blood, becoming collapsed, restless, and covered with sweat; the pulse was almost imperceptible. On the 6th she vomited some altered blood during the night. The pulse was 96 On the 21st the temperature had remained down and there had been no more hæmorrhage. She had been on full diet for two days and allowed to sit up in bed. On the 24th she was up in a chair. On the 26th more hæmorrhage occurred. Although she had been on liquid or semi-solid food and seemed to progress favourably, being bright and cheerful and free from fever, she had another attack of hæmorrhage on the night of Oct. 5th and on the night of the 6th she brought up about three ounces of blood On the 7th she brought up a few clots on vomiting in the morning. The heart was more dilated, the apex being felt an inch outside the nipple line in the sixth space At the apex there was a systolic and diastolic murmur, *the former not* being conducted into the axilla. A marked diastolic thrill was now felt over the left border of the sternum and the diastolic murmur was very much louder. On the 10th she brought up over a pint of blood with vomiting, became very pale and collapsed, and died quietly in a few soon relapsed into a drowsy or indifferent state; she had frontal headache and pain in the back; her cheeks were flushed, her tongue was coated, white, and tremulous. The bowels, which had been constipated all through the illness, were opened freely on the previous day after calomel, but the stools were not characteristic. There were no "spots" nor had there been any. The abdomen was rather retracted than distended. The menses were said to be regular. The urine was acid, of specific gravity 1024, and deposited phosphates; it contained no albumin. There were no abnormal chest signs or symptoms and no enlarged glands; the spleen was palpable, but seemed to be elongated rather than full.] On Oct. 31st, at 10 A.M., the temperature was 101·6° and the pulse was 84; at 10 P.M. the temperature was 100·6° and the pulse was 68. On Nov. 1st, at 10 A.M., the temperature was 100·4° and the pulse was 60; at 10 P.M. the temperature was 100·2° and the pulse was 72. On the 2nd the patient lay in a condition similar to that at the time of admission. No definite relief was obtained from a mixture of antipyrin and caffein; there was no action of the bowels; there were some vomiting and difficulty in feeding. Mr. W. Griffin reported that there was no appearance of optic neuritis or other eye symptoms. An enema of olive oil was given. At 10 A.M. the temperature was 99·0° and the pulse was 72; at 10 P.M. the temperature was 102·0° and the pulse was 65. On the 3rd the stupor had deepened and the patient resented interference; the evacuations, passed unconsciously, were semi-solid, light-coloured, and small. At 10 A.M. the temperature was 100·4° and the pulse was 72; at 10 P.M. the temperature was 100° and the pulse was 112 On the 4th it was recorded that she had been in a profound stupor all night, but that this morning she answered questions, opened her eyes, showed her tongue, and seemed to be conscious for a short time; she said at first that she had no pain, but later she complained of her head; the knee-jerks were brisk; she took food better. At 10 A.M. the temperature was 100·6° and the pulse was 80; at 10 P.M. the temperature was 100·2° and the pulse was 78. On the 5th it was recorded that she was unconscious all night; her limbs were rigid at times and her breathing was stertorous; she had to be fed by a nasal tube; urine was passed unconsciously; and there was some spasmodic contraction of the left side of face. At 10 A.M. the temperature was 101·4° and the pulse was 96; at 10 P.M. the temperature was 101·2° and the pulse was 120. On the 6th, early in the morning, she seemed to be choking and convulsions set in, affecting mostly the head and right arm; she was much cyanosed and there was double internal strabismus; frothy vomiting of a coffee-ground character occurred and continued at intervals till death, which took place at noon. At 10 A.M. the temperature was 100·2° and the pulse was 160. From Oct. 30th to Nov. 4th the respirations varied from 16 to 24 per minute; on Nov. 5th the highest rate was 30 per minute.

---

[1] A paper read before the Society for the Study of Disease in Children on Nov. 15th, 1901.

At the necropsy made on Nov. 7th the brain was found to be rather soft; there was some hyperæmia of the meninges; there was no tumour, lymph, pus, or hæmorrhage, but there were many small, very recent, tubercles along the vessels in both Sylvian fissures, which were not glued together; there was no ventricular effusion. There were old pleuritic adhesions over the lower half of the right lung; there was marked puckering at the apex, and on section a hard calcareous nodule was found of the size of a large pea. There was marked emphysema above the level of the adhesions. Both bases were congested but not solid. In the heart the right ventricle was somewhat dilated; the left was contracted and hypertrophied; there were numerous small transparent, bead-like vegetations along the edges of the mitral valve. There was a slight excess of pericardial fluid. The small intestine showed no sign of ulceration, but there were congestion and scattered miliary tubercles in the lower part of the ileum. There were several enlarged, hard, and injected mesenteric glands. The spleen weighed 12 ounces; it was thin and enlarged lengthwise, but was otherwise normal. (For most of the above notes I am indebted to Mr. P. Foster and Mr. P. M. Perkins, resident officers.)

*Remarks.*—Although the clinical picture soon after admission was one of meningitis there was much room for doubt in the earlier stages and this doubt was presumed to be cleared up by the Widal test. The present case, together with some few other cases recorded, must tend to qualify the confidence at present reposed in it. The Ehrlich diazo test I have found very much less trustworthy and did not use it. The tuberculosis serum test as propounded by Arloing, Romberg, and others is not yet sufficiently proved to work by, and lumbar puncture did not seem to be justified. I regret that the blood was not examined for the leucocytosis, &c., described by Dr. Bastian. In the absence of lung-signs a further difficulty lay in the mode of onset, since, as Sir Thomas Barlow writes, "this is usually *insidious* in those in whom some latent local tubercle has been consistent with moderately good health—*abrupt* in those whom advanced disease has brought to an emaciated condition" (which was not so here). Another remark of his, however, was well illustrated by the appearances found at the necropsy—namely, in tuberculous meningitis "tubercle in various stages co-exists in many organs of the body ...... in some parts contemporaneous with that in the membranes of the brain ...... in other parts of older date."

## LONDON TEMPERANCE HOSPITAL.

### A CASE OF TRAUMATIC LACERATION OF THE RIGHT KIDNEY; LUMBAR EXTRAVASATION; PARTIAL NEPHRECTOMY; COMPLETE RECOVERY.

(Under the care of Dr. W. J. Collins.)

Rupture of a kidney inevitably leads to the effusion of blood and urine into the perinephric tissues, and the abscess which follows requires an incision for the release of the pus. The treatment of the damaged kidney will depend on the extent of the injury. If the laceration is severe early complete nephrectomy is strongly indicated; on the other hand, if the kidney substance is only partly lacerated, so that the fragments are still connected by the pelvis, the several fragments should be sutured together. There are, however, intermediate cases in which the injury to the kidney is such as to justify an attempt to retain the organ, but one or more detached or almost separated fragments of kidney substance may be present. In these cases an endeavour should be made to save part of the kidney while removing that portion which is incapable of recovery. This operation of "partial nephrectomy" is comparatively modern, one of the earliest recorded cases, if not the earliest, having been performed by Mr. C. R. B. Keetley[1] in 1890. Several other cases are mentioned by Mr. H. Morris,[2] and it is probable that the operation has been performed many times without having been recorded.

A woman, aged 31 years, was knocked down by a horse and van on Oct. 13th, 1900, one of the wheels of the van passing over her abdomen. She was taken home and was attended by her medical adviser, but alarming symptoms of abdominal pain and collapse supervening she was admitted into the London Temperance Hospital under the care of Dr. W. J. Collins at half-past eight the same evening. The abdomen was full, resistant, and tender (especially in the right lumbar and inguinal regions). The catheter drew blood mixed with the urine. The patient was frequently sick before and after admission and there was some hiccough. For the next two or three days she continued to be in much the same state; but the collapse passed off, and though some sickness continued, the tenderness and resistance in the right lumbar region became less, the urine ceased to be sanious, and the bowels acted naturally.

On Oct. 22nd aspiration of the right loin drew off four and a half ounces of rather offensive blood-stained urine of a specific gravity of 1020, and on the 23rd under chloroform Dr. Collins made an incision five inches long in the right loin in the ilio-costal space, and cutting down to

---

[1] The Lancet, Jan. 18th, 1890, p. 134.

[2] Surgery of the Kidney and Ureter, vol. i., p. 191.

At 4 P.M. I returned to see how the patient was and found her to be doing well. I then proceeded to examine the body of the fœtus. An incision into the boggy tissues of the scalp showed that the skull was intact, but that the scalp was very œdematous over it. Indeed, the whole skin surface of the child's body was distended to the utmost with anasarca and the face was quite distorted. On opening the abdomen, which measured 15 inches in circumference, a large quantity of ascitic fluid burst out, and the thorax was also full of dropsical fluid I removed one kidney and found it lobulated, but on section it did not show any morbid appearance. The mother made an uneventful recovery, the dropsy passing off in a few days and the albumin disappeared from the urine. This was the sixth pregnancy and the patient had given birth to several healthy children, though the fourth and fifth pregnancies had been abnormal.

The case is instructive in showing what great difficulties may be overcome by persistent traction and counter-pressure over the uterus. A real advantage might be gained in such cases by carefully introducing an instrument with the object of puncturing the child's abdomen when it was discovered to be enlarged by the operator's internal hand, but this would be a delicate and not very easy procedure and would almost require a special trocar and cannula for the purpose. In cases of fœtal dropsy the child invariably dies soon after, if not before, delivery, so that saving the infant's life is not a question to be much thought of.

I regard the case as one of primary dropsy of the ovum and secondary dropsy of the mother, caused in her case by pressure of the enlarged uterus upon her kidneys and abdominal blood-vessels. I am quite at a loss to account for the fœtal condition, and as the literature of the subject appears to be very scanty I should be glad to have a little light from someone of wider experience and knowledge on the etiology of such cases

### A CASE OF ACUTE SUFFOCATIVE PULMONARY ŒDEMA.

By FREDERICK W. ROWLAND, M.D. DURH.

DR. JOHN LINDSAY STEVEN'S clinical lecture on Acute Suffocative Pulmonary Œdema reported in THE LANCET of Jan 11th, p. 73, brings to my mind a case I saw recently which I think must be an example of this disease. If so, it shows again how it may suddenly attack a previously healthy person. It also shows that it may rapidly prove fatal.

Arriving at a house at 3 A.M. one day I found the old man whom I had been called to see lying in the semi-recumbent position, dead. The history was that he had been in perfect health till the previous day, when he had complained of feeling unwell and had said that he thought he had a cold; but he went to bed and fell asleep as usual. About midnight, however, he awoke and complained of difficulty in breathing. This became rapidly worse He was now expectorating copiously. His wife put on a mustard poultice to ease his breathing, but he died about 2 A.M. almost before his relatives realised how ill he was He was a thin, slightly-built man, 65 years of age. The spittoon contained about six ounces of frothy, yellowish, serum-like fluid.

I made a post-mortem examination later in the day. On the right side of the chest there was a small quantity of fluid in the pleural cavity The left lung was fixed by old adhesions to the chest wall. Both lungs were markedly œdematous, but the left was much more so than the right There were no phthisical scars at either apex. The trachea and bronchial tubes were full of white froth and yellowish serum. The kidneys were healthy The capsules stripped off easily without taking any kidney substance with them. The surfaces beneath were not quite smooth and there were one or two cysts on one of them but the amount of cortex was good and there were no signs of granular degeneration. Neither was there any visible hyperæmia. The other organs were healthy.

May not this have been a case where the fatal result was brought about through the feebleness of advancing age before the expectoration had time to become blood-stained? The patient was said to have had good health for many years, and his wife did not know that he had suffered from pleurisy.

I must confess to considering it a case of acute inflammatory œdema at the time, after looking it up in the text-books, but it certainly does not come under that heading as defined in Wilks and Moxon's "Pathological Anatomy," third edition, p. 339.

Brighton.

### A CASE OF VAGINA DUPLEX.

By EDGAR W. SHARP, M.B. GLASG.,

SENIOR HOUSE SURGEON, BURY INFIRMARY, LANCS.

WHILST operating on a woman, aged 41 years, for a fissure of the anus and also hæmorrhoids an unusual fleshy projection was observed situated between the labia This led to an examination which revealed a condition of vagina duplex. The vagina was divided by a fleshy partition running from before backwards and from the cervix uteri, where it was somewhat thin and membranous, to the vaginal orifice, where it was almost half an inch in thickness. The greater part of the septum on both sides was covered with the corrugated mucous membrane of its respective half of the vagina. There was a small communication near the cervix between these two halves. The cervix uteri was somewhat small. There were no distinct fornices and the os uteri was situated on the left side. On examination bimanually and per rectum the uterus was found to be small, but otherwise apparently normal. The patient had had no difficulty with menstruation; she was married, but had never been pregnant.

Bury.

### THE WIDAL REACTION IN TUBERCULOUS MENINGITIS.

By EDWARD MACKEY, M.D. LOND.,

PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL AND CONSULTING PHYSICIAN TO THE ROYAL ALEXANDRA CHILDREN'S HOSPITAL, BRIGHTON.

THE following case seems of sufficient importance to be recorded, since it is customary to consider the Widal reaction as a reliable help in what is often a difficult matter—namely, the diagnosis between enteric fever and meningitis. It is not always that a history so complete can be secured as in the present case.

The patient, a single woman, 28 years of age, was sent into the Sussex County Hospital as a case of enteric fever by her medical attendant, mainly on the strength of a positive Widal reaction obtained in the Brighton Corporation laboratory. I am informed that the dilutions employed there are 1 in 10 and 1 in 30, with a half-hour limit, and a record is usually kept, but in the present instance the counterfoil of the certificate was, through an oversight, not properly filled up, so that an exact statement on this point is not now possible; the Sussex County Hospital notes show, however, that on Nov. 2nd a positive reaction was obtained with a 1 in 10 dilution in 10 minutes and with a 1 in 20 dilution in 20 minutes by Mr P M Perkins, the resident pathologist

The patient was admitted on Oct. 30th, 1901, and was said to have been ill for 14 days chiefly with headache and vomiting, which still continued more or less She had had no illness requiring attention during the past two years, and she gave no history of chest trouble but of "hip-disease" at the age of nine years, the result of which might be traced in an old backward dislocation at the knee. Her father had died from cancer; her brother and sister were healthy. There was no other illness in the establishment where she lived and no cause was known for her present attack; her only previous complaint was of rather frequent headache for some time past On admission her temperature was 101·2° F., her pulse-rate was 76, and her respirations were 24 She lay in bed on her side, with her head, which was rather retracted, turned away from the light, pressing against the pillow. She opened her eyes when asked a question and answered "Yes" or "No," but to penetrate. With regard to the second point it was remarkable in how large a proportion of cases the patients were of intemperate habits or the attack had followed some excess or error of diet. It had also supervened on cancer, ulceration of the lower end of the œsophagus, and injury. The source of the virulent organisms did not appear to have been ascertained in any of the cases; dental suppuration connected with the teeth and jaw might be a possible cause in some cases. He was not aware that any fatal case had been diagnosed during life. Dr. Dörbeck claimed to have diagnosed a case which recovered, mainly from the presence of pus in the vomit. The symptoms to be expected would be epigastric pain and tenderness, dilatation of the stomach, vomiting, with possibly the presence of pus in the vomit, high temperature, and the supervention of acute general peritonitis, but these symptoms were by no means always present and in some cases the disease had run a latent course and the implication of the stomach was only discovered on post-mortem examination.

Mr. ALEXANDER G. R. FOULERTON read a paper on a case of Pneumococcic Gastritis, with some remarks on the Infection of Mucous Membranes by Diplococcus Pneumoniæ. The symptoms were those of septicæmia with petechial hæmorrhages in the skin. At the necropsy there were found numerous petechial hæmorrhages into the subcutaneous tissue, "mulberry spots" on the face and neck, petechial hæmorrhages on the epicardium and into the substance of the liver and kidneys, and an acute fibrinous exudation extending over the surface of the stomach. Cultures of diplococcus pneumoniæ were obtained (1) from the exudation on the lining of the stomach; (2) from one of the mulberry spots on the face; and (3) from an interstitial hæmorrhage into the right lung. Microscopic section of the wall of the stomach showed the formation of an exudation membrane, with an extensive necrosis of the glandular layer. The only similar case previously recorded was that by Dieulafoy who had described a case of pneumococcic ulceration of the stomach.

Mr. FOULERTON said that the submucous coat of the specimen shown by Dr. Cayley was infiltrated with pus and was at least three times thicker than normal.

Mr. S. G. SHATTOCK said that a similar case had been recorded by Mr. A. Q. Silcock as occurring after gastrostomy; the submucous membrane was in that case very much swollen.

Dr. A. G. AULD suggested that the condition of the stomach might have been due to a mixed infection.

Dr. F. W. ANDREWES said that there were many fibrinous exudations in which the pneumococcus could be demonstrated and he thought that Mr. Foulerton had correctly attributed the formation of this membrane to the presence of the diplococcus pneumoniæ.

Dr. H. D. ROLLESTON referred to the work of Dr. William Hunter on Phlegmonous Gastritis who held that the source of the infection was carious teeth. He asked Dr. Cayley what was the condition of the teeth in his case. He mentioned also the occurrence of duodenal ulcers in association with pneumonia; in these, however, the pneumococcus had not been demonstrated, and they were usually regarded as of toxic origin. He suggested also that the ulcers found in the colon were of the same nature.

Dr. HAROLD SPITTA read a short paper, illustrated by a series of lantern slides, on the Bacteriology of a case of Rapidly Spreading Gangrene without Emphysema which recently occurred in St. George's Hospital as the result of a lift accident. The wound was very much contaminated with dirt and was of an extensive nature, and involved a fracture of the four outer metacarpal bones and the lower third of the radius. From the pus he isolated in a pure state a square-ended, non-sporing, gas-producing, capsulated, anaerobic bacillus, which on inoculation proved highly virulent to guinea-pigs, death resulting in 15 hours. He was able to recover this organism from the subcutaneous, pleural, and peritoneal glands, and also in pure culture from the heart blood of the animals inoculated. It was a strict anaerobe, grew well at 37° C., and more slowly at 21° C. Most of the ordinary laboratory media proved suitable for its cultivation, especially those containing glucose and traces of sodium formate. Both sugars and carbohydrates were fermented, and in the former tubes gas production was always very excessive. In glucose formate bouillon growth was always very rapid, a dense turbidity with a thick ropy sediment being found in addition to much gas formation. On potato the organism formed a transparent, almost invisible, film, but in milk and on gelatin at 21° C. no growth was ever obtained. On solidified serum the bacillus grew well, forming, as on agar, small, discrete, circular, non-liquefying colonies of a greyish colour about three-quarters of a millimetre or so in diameter. The organism never stained well by the method of Gram and seemed always very prone to decolourise in small dots. Considering its pathogenicity and certain of its cultural characteristics Dr. Spitta suggested its resemblance to Welch's bacillus aerogenes capsulatus, though clinically the marked absence of emphysema was not in accordance with typical cases of infection with Welch's organism. In conclusion, he commented on the extreme difficulty he had experienced in preserving the vitality of the organism for more than a few generations outside the body, and remarked that he believed that this had been the experience of others. —Dr. W. BULLOCH said that he had examined several such cases as that recorded and had isolated a similar bacillus. He had experienced great difficulty in obtaining the organism in pure culture and it died out very rapidly. The organism he had isolated stained well by Gram, and although these slight differences were present he considered that in all probability it was the bacillus described by Welch.

Dr. W. BULLOCH made a communication on the Transmission of Hæmolysins from Parents to Offspring. The hæmolysins were prepared by injecting the blood of the ox into rabbits, the serum of the latter acquiring a hæmolytic power towards the corpuscles of the ox. The hæmolysin was compound and depended for its action on two bodies—viz., the amboceptor and the complement. Immune males did not propagate their immunity to their offspring by normal females. Hæmolytic females immunised anterior to the conception gave birth to young the blood-serum of which was also hæmolytic. The milk was not hæmolytic in the native state, but in complementing it with normal serum Dr. Bulloch had found that it contained relatively large quantities of immune body.—Dr. AULD asked if the immune body introduced into the stomach with the milk passed directly as such into the blood without alteration.—Dr. BULLOCH said that in young animals the immune body passed into the blood from the stomach without undergoing any alteration. As an instance of this he said that young animals sucking milk from a mother immunised against tetanus acquired a very considerable immunity against tetanus.

---

## LARYNGOLOGICAL SOCIETY OF LONDON.

### *Exhibition of Cases and Specimens.*

A MEETING of this society was held on Jan. 10th, Dr. E. CRESSWELL BABER, the President, being in the chair.

Dr. A. BRONNER showed a specimen of a Pedunculated Angeioma of the Larynx in a man, aged 63 years. Excessive hoarseness was the only symptom. The growth was raspberry-like in appearance and size and was removed by forceps. Microscopical examination showed it to be a nævoid growth in the mucous membrane.

Dr. SCANES SPICER showed a case of Saddle-nose treated by subcutaneous injections of vaseline. The technique of this treatment was explained thoroughly and the danger of the vaseline passing upwards into the eyelids was pointed out. This accident had occurred in the present case, but otherwise the treatment had been most successful, the patient having a well-shaped nose.—Mr. P. R. W. DE SANTI suggested that a piece of lead sheeting should be applied over the parts adjacent to the root of the nose and that firm pressure should be exerted on it during the injection of the paraffin, in order to overcome the likelihood of the paraffin passing into the eyelids.—Dr. H. LAMBERT LACK thought that it might be possible to raise the skin and to make a small cavity into which to inject the paraffin.

Dr. SCANES SPICER also showed (1) a case of Multiple Suppurative Sinusitis and Polypoid Disease of the Nose, for the relief of which radical operations had been undertaken with success; and (2) a case of Bony Thickening over, and Polypi within, the Right Frontal Sinus in a man, aged 46 years, for which a radical operation had been performed. This was followed by a recurrence of the bony growth and the commencement of similar symptoms on the opposite side of the face.

Dr. W. MILLIGAN showed: 1. A specimen of Lipoma of the Pharynx which extended upwards behind the level of the soft palate and downwards behind the larynx. The tumour was removed successfully by lateral incision in the kidney turned out a large quantity of blood-clot and some urine escaped. A portion of the kidney as large as a walnut, together with some smaller fragments, were found torn off from the rest and were removed. A careful examination of the remainder showed that though contused it was not hopelessly damaged and the ureter appeared to be intact; it was accordingly left. The wound was thoroughly irrigated and a large drainage-tube was inserted and lightly packed around with iodoform gauze. The wound was dressed two or three times a day and at first was urine-soaked; incontinence of the vesical urine had been present from the first and persisted, but the amount passed rarely exceeded two pints in the day. On Nov 11th the urine collected from the wound was acid, that from the bladder being alkaline, and there was some cystitis; the general condition was rapidly improving. At first some seven ounces of urine were collected daily from the wound; this diminished progressively and by Dec. 4th urine had ceased to come from the wound and on the 11th the wound was healed. The patient was discharged on Jan. 1st, 1901; on the three days previously she had passed 63, 58, and 53 ounces of urine.

## NORTH WIMBLEDON COTTAGE HOSPITAL.

### A CASE OF TETANUS SUCCESSFULLY TREATED WITH ANTITOXIN.

(Under the care of Dr. J. E. BATES.)

THE intra-cerebral injection of tetanus antitoxin cannot be said to have passed the experimental stage, and there is no indication of the spread of this method of administering anti-tetanic serum. Certainly some of the cases in which it has been employed are very striking,[1] but the increased risk is commonly felt not to be compensated by any increased efficiency. Into the question of the value of the serum itself we need hardly enter, it is recognised that when administered early and freely benefit results, but that in many cases its employment does not prevent a fatal result. We appreciate the importance of Dr. Bates's case recorded below, but we must not too hastily attribute the favourable issue to the serum or its mode of administration.

A youth, aged 16 years, first came under the care of Dr. J. E. Bates in the North Wimbledon Cottage Hospital on June 11th, 1901, for a compound Colles's fracture of the right arm. The fracture had occurred on the afternoon of that day, about one hour before Dr. Bates saw him. He was a lad occupied on some buildings which were being erected on the site of an old nursery garden. He met with the accident through falling off a scaffold, and when seen the lower end of the ulna had pierced and was protruding through the skin, shirt, and coat-sleeve, both the end of the bone and the coat-sleeve being covered with mud. A temporary dressing, consisting of a very dirty piece of rag, had been placed over the broken end of the bone. After a very careful cleansing of the wound, a nail-brush being used and an anæsthetic being given, the fracture was reduced after some difficulty and put up in splints. Three days later (on the 14th) there arose much swelling, œdema, and general redness of the forearm and hand with an evening rise of temperature to 102° F. All these symptoms soon subsided under hot boric fomentations although the wound still continued to discharge freely.

Eleven days after the injury (on June 22nd) the patient noticed that the muscles of his jaw were a little stiff; but the stiffness was so slight that he omitted to mention it to Dr. Bates when he saw him on that day. The next day (the 23rd) the symptoms had materially increased. He could only get his mouth half open, and this caused him pain. Both sterno-mastoid muscles were tense and he also had difficulty and pain when trying to swallow fluids. On the 24th there was an alarming increase of all the symptoms. The jaw was closed tightly, swallowing of fluids caused choking and dyspnœa and was very painful, the muscles connecting the head and trunk anteriorly and posteriorly were all absolutely rigid, and he complained of painful jerky spasms in his right arm. Dr. Bates saw him in consultation with Mr. E. Pocklington and Mr. R. T. P. Collyns of Wimbledon, and it was decided to give him the benefit of antitoxin without delay.

On June 24th, at 5 P.M., assisted by Mr. Pocklington and Mr. Collyns, Dr. Bates trephined the patient over the right parietal bone anteriorly and injected five cubic centimetres of antitoxin (obtained from the Jenner Institute of Preventive Medicine) into the right lateral ventricle of the brain, and at the same time 35 cubic centimetres of the antitoxin were injected into the loins. The patient stood the operation well and a marked quickening of the pulse was noticed during the intra-cerebral injection. During the night after the operation the pulse-rate rose to 116; but it had dropped to 98 on the next morning and never rose above 100 subsequently. The temperature once after the operation rose to 99·6°, but never higher. For 48 hours after the operation the symptoms showed no signs of amelioration, but, on the other hand, they became no worse. On the 27th (three days after the operation) improvement set in in all the symptoms and was steadily maintained so that by July 6th (12 days after the operation) the patient was allowed to eat solid food and to sit up out of bed. On July 1st (seven days after the operation) the wound in the head was dressed for the first time and found to be completely healed by first intention.

*Remarks by* Dr. BATES —The points of interest in this case I think are these: (1) the dates of the exciting cause and onset are quite clear and distinct; (2) the patient at the time of the accident was living an outdoor life and was in robust health; (3) the patient all through the illness never failed to take his nourishment well, although part of the time he had great difficulty and pain in doing so; and (4) the rapid onset of the symptoms, their speedy and alarming progress, the manner in which the injection checked their progress and also the patient's comparatively swift and entire recovery. Finally, I must tender my sincere thanks to Mr. Pocklington and Mr. Collyns, without whose advice and assistance I feel sure the patient would not have made such a rapid and complete recovery from such an awful disease

# Medical Societies.

## PATHOLOGICAL SOCIETY OF LONDON.

*A Case of Phlegmonous Gastritis due to Streptococcus Infection.—A Case of Pneumococcus Gastritis with General Infection.—The Bacteriology of a Case of Rapidly-spreading Gangrene.—The Transmission of Hæmolysins from Parents to Offspring.*

A MEETING of this society was held on Jan. 21st, Mr. W. WATSON CHEYNE, the President, being in the chair.

Dr. W. CAYLEY related a case of Phlegmonous Gastritis due to Streptococcus Infection. The patient, a woman, aged 26 years, was admitted into the Middlesex Hospital on Nov. 19th and died on Nov. 21st. She had been taken ill without any assignable cause on Nov. 13th with rigors, sore-throat, headache, and pain in the abdomen and limbs. On the 17th she began to vomit and continued to do so on the 18th; the vomiting was accompanied by severe abdominal pain. On admission she presented all the symptoms of acute general peritonitis with dilatation of the stomach. Her temperature was 104 6° F. She gradually sank and died on the 21st. She had no vomiting or action of the bowels after her admission. At the necropsy there was general suppurative peritonitis; the stomach was dilated and its coats were thickened. On section there was purulent infiltration of all the coats of the stomach between the mucous membrane, which appeared intact, and the peritoneum; this change was most marked over the pyloric third of the organ. Bacteriological examination of the purulent exudation from the submucous coat showed a number of bacilli which did not stain by Gram's method and which resembled morphologically bacillus coli communis; there were also present a few short chains of streptococci which stained by Gram's method. The other organs presented nothing abnormal. It was probable that the streptococcus infection was primary and the bacillus coli a secondary effect. Dr Cayley referred to the cases of phlegmonous gastritis collected by Dr. R. F. C. Leith in Vol. IV. of the Edinburgh Hospital Reports and to some which had been published since. Two conditions were necessary, the presence of virulent organisms and a condition of the mucous membrane which would allow them different medical men: one was apparently cured by turpentine gauze intra-uterine packs. Dr. Briggs maintained that collective investigation after the operation of curettage was required to remove doubts as to its present position in minor gynæcological, and especially in obstetrical, surgery.—Dr. W. MACFIE CAMPBELL generally used the loop curette or Donald's flushing instrument. Preferably he curetted first and then washed out; débris was removed with antiseptic gauze and the uterus was packed with the same. His best results were in removal of placental remains in abortion cases; in cases of metrorrhagia he had often been disappointed.—Dr. JOHN E. GEMMELL regarded the finger as the best curette for diagnostic and obstetric purposes, preceded by dilatation of the cervix. He considered, however, that the curette had its place when used intelligently; it was important to weigh carefully the evidence for the true causation of the local condition. Microscopical examination of the tissue removed was most important, especially when considered in conjunction with the feeling imparted through the curette during the operation. —Mr. G. A. HAWKINS-AMBLER said that endometritis was a sufficiently defined condition, and the obstacles in the way of cure after curettage lay in the tendency of medical men and patients to look upon the operation as the end, rather than the beginning, of treatment. He felt that the finger, although the best curette in post-abortion cases, was not always effectual, except in very early cases. The differential diagnosis between adenoma and adeno-carcinoma was not possible in many cases from the examination of mere curettings.—Dr. DAVIES, Dr. A. C. WILSON, and Dr. A. STOOKES also spoke and Dr. BRIGGS replied.

## LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

*Partial Nephrectomy.—Injury to Head.—New Gynæcological Instruments.—Exhibition of Cases and Specimens.*

A MEETING of this society was held on Jan. 10th, Dr. A. G. BARRS, the President, being in the chair.

Mr. B. G. A MOYNIHAN read a paper on Three Cases of Partial Nephrectomy. In the first case a solitary cyst of the lower pole of the right kidney was excised; in the second an inflammatory myxo-sarcoma of the lower half of the right kidney was removed; and in the third a solitary cyst in the transverse band of a horse-shoe kidney was excised. All three cases recovered. In the second case the naked-eye appearance suggested tubercle. A portion of the pelvis of the kidney was also removed, the wound which was left being closed by a continuous catgut suture. In all the cases a wedge of kidney substance was removed and the wound which was left was closed by interrupted catgut sutures. Reference was made to the records of similar cases.—Dr. MAULE SMITH. Mr. W. H BROWN, Mr. H. LITTLEWOOD, Dr. JASON WOOD, and the PRESIDENT took part in the discussion.

Mr. BROWN read notes of two interesting cases of severe Head Injury in which complete recovery ensued.—Dr. F. W. EURICH, Dr. STEWART, Dr. STEVEN, Dr. A. L. WHITEHEAD, Dr. E. F. TREVELYAN, and the PRESIDENT took part in the discussion.

Mr. C. J. WRIGHT showed the following New Gynæcological Instruments—1. A new form of Urethral Speculum which he had found useful in examination and removal of caruncle of the female urethra. It was made on the principle of the duck-bill speculum and was more convenient and less painful than the bivalve or ordinary vulcanite form. 2 A pair of Locking Angular Forceps useful in the examination of, and application of mops and tampons to, the cervix uteri through the speculum. 3. A Metal Box opening with a spring, which could be opened and shut with one hand, for the administration of chloroform by the practitioner in attendance on labour. It provided a ready means of giving chloroform, economising the anæsthetic and preventing its diffusion into the room when shut; it also preserved the chloroform ready for immediate and intermittent use, and the anæsthetic could be discontinued at a moment's notice.

The PRESIDENT showed a Gall-bladder from a case of Perforative Cholecystitis. There were ulcerations and a small perforation on the under surface of the gall-bladder which set up a general peritonitis. The common duct and gall-bladder were both packed with stones.

The PRESIDENT also showed specimens, with drawings, from a case of Henoch's Purpura. There was a large retro-peritoneal hæmorrhage probably originating in the suprarenal capsule and involving the tissues round the right kidney. There were also extensive hæmorrhages into the renal parenchyma as well as small hæmorrhages in the heart and lungs and particularly beneath the mucous membrane of the intestines. The symptoms during life were vomiting, abdominal pain, slight joint symptoms, and extensive purpura.

Dr. TREVELYAN showed a case of Early Locomotor Ataxia with Aortic Disease in a man, aged 50 years. Seven years ago this patient had a hæmoptysis and there was at the present time evidence of some old quiescent disease at the left apex.

Dr. TREVELYAN also showed a case of Locomotor Ataxia in a man, aged 39 years, in which the symptoms were improving under Frenkel's exercise treatment. The ataxia was only of a few months' duration.

Other cases and specimens were shown by Mr. CONSTABLE HAYES, Mr. LITTLEWOOD, Mr. BROWN (with Mr. J. PICKLES), Mr. A. J. POLLARD, and Dr. J. ALLAN.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

*Exhibition of Cases and Specimens.—Removal of a Cerebral Tumour.*

THE fourth ordinary meeting of this society was held on Jan. 15th, Dr. JAMES ANDREW being in the chair.

Dr. BYROM BRAMWELL demonstrated two cases of Syringomyelia. He noted that they were examples of a rare disease, although lately he had had a run of such cases. 1. The first case was that of a youth, aged 17 years, who showed atrophy of the small muscles of the hand; the bird-claw appearance which was so suggestive of the disease was present. The palpebral fissure on the left side was much smaller than was that on the right side, the left pupil was narrower, and the left eye was less prominent as a whole than was the right. The fact of the affection of the sympathetic nerves and the condition of the hand being present at the same time suggested to Dr. Bramwell that this was a case of syringomyelia. All the characteristic features were present: the loss of power in the left hand which had lasted for about a year together with the muscular atrophy. The patient had suffered from incontinence of urine since childhood, and four years ago he had been treated for tuberculous disease of the hip-joint. Disturbances of æsthesia were characteristic of this disease. In this case there was no disturbance of tactile or of painful sensation. Over the left arm, the neck, the front of the chest, and the back, as well as in some other localities, the appreciation of heat and cold was lost. There was a great exaggeration of the deep reflexes in the lower extremities, ankle clonus being present. The lad presented a stumpy and broad appearance, and this had been noted as a characteristic in many cases of syringomyelia. The lesion was situated in the cervical and upper dorsal regions of the cord. 2. The second case was that of a woman, aged 30 years, who had been transferred from Professor T. Annandale's ward in the Edinburgh Royal Infirmary to Dr. Bramwell. She had suffered for a considerable time from sores on the hands and feet—one under the ball of the big toe had persisted for a year. These sores recurred on the palms and fingers of both hands and were not painful. Several of these had developed spontaneously; one recent one resulted from her putting the hand into hot water. This patient presented the same alterations as were observed in the previous case but they were more extensive. Over the upper half of the body as well as in other regions the heat-sensation was lost entirely. The biceps and other muscles of the left shoulder girdle were markedly wasted. The pupils were unequal and the deep reflexes were greatly exaggerated, the jaw-jerk being present Briefly, the symptoms were in this case disassociated anæsthesia, muscular atrophy, trophic changes, alteration of pupils, and great exaggeration of the deep reflexes.

Mr. HAROLD J. STILES exhibited: 1. A boy after operation for a Punctured Wound of the Brachial Artery opposite to the origin of the superior profunda artery. The wound, which was half an inch in length and which lay over the course of the brachial artery, was enlarged. The basilic vein and the

the neck. 2. A microscopical section of a Fibro-sarcoma of the Right Vocal Cord in a male, 61 years of age. After a preliminary tracheotomy, thyrotomy was performed and the growth was removed successfully, and there was no recurrence 12 months later. It was reported to be a fibro-sarcoma by the Clinical Research Association. Some doubt as regards the diagnosis in both these cases was raised, and Dr. Milligan consented to place the specimens in the hands of the Morbid Growths Committee. 3. x-ray photographs of a Plate of Teeth lodged in the Larynx, a Rubber Tube in the Maxillary Antrum, and a Eustachian Catheter in the Frontal Sinus.

Dr. **HENRY SHARMAN** showed specimens of Papilloma of the Tonsil and of the Posterior Pillar of the Fauces. Under the microscope it was clearly seen that the papilloma of the tonsil grew from the surface of the tonsil proper and not from the interior of a lacuna.

Dr. **ATWOOD THORNE** showed a Self-looping Nasal Polypus Snare made at his suggestion by Messrs. Mayer and Meltzer.

Dr. **W. JOBSON HORNE** showed a case of Nasal Obstruction in a woman, 24 years of age. Inferior turbinectomy had been performed six years previously, giving roomy inferior passages, but there was narrowing of the upper passages due to enlargement of the middle turbinate. Dr. Horne thought the case interesting in relation to the observations of Mr. C. A. Parker on the direction of the air-currents in the nose, and he also raised the question as to whether the hypertrophied middle turbinate could be secondary to the removal of the inferior turbinate.—Dr H **TILLEY** and Dr. **SCANES SPICER** were of opinion that the difficulty of inspiration was due to collapse of the alæ nasi, and a discussion ensued upon the best method of treating this deformity.

Dr. **S. H. SNELL** showed a case of Herpes of the Palate.

Dr. **J. DONELAN** showed a case of Syphilitic Laryngitis in a man, aged 52 years. In spite of energetic anti-syphilitic treatment the local condition had become worse and Dr. Donelan raised the question as to whether it had become malignant.

Mr. **DE SANTI** showed a case of very extensive Destruction of the Interior of the Nose due to Tuberculous Ulceration in a woman, 51 years of age The patient was suffering from pulmonary phthisis, but at the same time she showed evidence of syphilis in the pharynx. He suggested that this was a case of mixed infection.—The **PRESIDENT** suggested the advisability of examining the sphenoidal sinus, as he did not think that tuberculosis alone would produce the condition seen.—Dr. **H. W. FITZGERALD POWELL** had no doubt that the case was one of tertiary syphilis.

Dr. **F. W. BENNETT** showed a case of Ulceration of the Nasal Septum. The case was of long standing and had been under observation since 1898. There was marked pain in the nose, especially on the right side, where the tissues were considerably swollen. The septum was perforated and the nostril was filled with muco-purulent secretion. The patient had been treated by means of local application, tonics and iodides, but without benefit. The question raised was the nature of the ulceration. Opinion was divided as to whether it was simple, tuberculous, or syphilitic.

Dr. **J. DUNDAS GRANT** showed a case of New Growth on the Tonsil in a woman, aged 32 years.

---

# LIVERPOOL MEDICAL INSTITUTION.

*Exhibition of Cases and Specimens.—Graves's Disease.—Malaria.—Uterine Curettage.*

A MEETING of this society was held on Jan. 16th, Mr. **RUSHTON PARKER**, the President, being in the chair.

Dr. **EDGAR STEVENSON** showed a girl, aged 15 years, with almost complete Palsy of the External Ocular Muscles. There was marked convergence of the eyes on any attempt to raise the head or to move them. Considerable improvement had resulted from four applications of a high frequency current, the patient now having binocular distant vision.

Dr. **STEVENSON** also showed a woman, aged 25 years, from whom the right lobe of the thyroid gland had been removed four years ago The general symptoms had improved greatly, but the exophthalmos had steadily increased to quite an unusual degree. The corneæ were unaffected and her vision was normal.—Mr. **C. H. B. SHEARS** said that excision of part of the thyroid gland had produced no improvement in the exophthalmos and asked what was the present position of thyroidectomy in these cases. It was remarkable that vision and the mobility of the eyeballs were normal, for the stretching of the optic nerve and external muscles must be extreme.—Mr. **R. J. HAMILTON** noted the perfect closure of the lids in this case and drew attention to the unsatisfactory results of operative treatment for goitre when marked exophthalmos was present.

Dr. **W. CARTER** narrated a case of Graves's Disease in a young man, in which cure resulted, he believed, from the exhibition of diluted hydrofluoric and hydriodic acids. Dr. Carter also mentioned two cases in which partial thyroidectomy was performed; in one death followed in a few days, in the other four years after the operation the symptoms were apparently unchanged.—Dr. **J. R. LOGAN** had seen a case of Graves's disease practically cured by a prolonged course of bromide of potassium and arsenic. He had seen two marked cases in one family.—Dr. **J. HILL ABRAM** said that he had seen marked improvement follow partial thyroidectomy, and in Dr. Stevenson's case the general symptoms were notably less than at the time the patient was under observation at the infirmary. Certainly in no other way did they get such speedy relief from the most dangerous symptoms.

Dr. **R. J. M BUCHANAN** described a case with recurrent attacks of fever in which there was no leucocytosis and in which one or two of the red cells contained a non-pigmented hæmatozoon. The patient had never been out of England but had been bitten freely by mosquitoes in Kent.—Major **ROSS** thought that the diagnosis of malaria was correct.—Dr. **CARTER** said that a former house physician, the late Dr. Henry Welch, had typical ague in 1880 after a few weeks' residence near Lancaster in early autumn, just after the valley of the Lune had been flooded.—Dr. **BUCHANAN** replied.

Dr. **H. BRIGGS** read a paper on the Uterine Curette and Curettage in Gynæcological and Obstetrical Surgery. He said that his paper was mainly founded on a consideration of the question, Was the modern estimate of the value of the curette as shown by its frequent use amply justified by known results? The results thereof were classified as (1) curative, (2) modifying, and (3) exploratory. After reviewing the tests applied to these results, Dr. Briggs said that the most satisfactory effects of curettage were obtained in the treatment of the uterus, sometime after abortion, by the removal of small pieces of chorion; subsequent microscopical investigation for detection of villi should be systematically carried out, otherwise many such cases were described as cures of endometritis. The best use of the curette was indicated by its inventor, Récamier, in 1850. The dull-curette of Gaillard Thomas was advocated by its inventor in the treatment of uterine "fungosities," an "omnibus" title for most affections of the endometrium known about the mid-period in the history of the curette. Since Nélaton, in 1853, followed by Savage, Routh, Olshausen, Bischoff, Matthews Duncan, and Herman (1880) had described cases of chronic hyperplasia, diffuse or polypoid, of the endometrium, many attempts had been made to differentiate glandular, interstitial, and mixed types of endometritis (Hunter Robb, 1896). Who could, even to-day, separate clinically endometritis, adenoma, and adenocarcinoma at a period when treatment or diagnosis by the curette was most important? The results of curettage in this particular were discouraging. Dr. Briggs thought that the estimate of the results of curettage, modifying or exploratory, depended, on the whole, more upon dilatation of the cervix to digital size and the use of the finger than upon the mere and otherwise imperfect scraping of the uterus by the curette. A description of the metal dilators used at the Hospital for Women, Liverpool, since 1888, was given; each dilator was made over four sizes of the English catheter scale in the first one and a half inches from the point. Dr. Briggs then discussed the results obtained in the treatment of metrorrhagia and showed sections of the endometrium from cases in which a classification might be attempted, but only on incomplete pathological evidence. He alluded to the thickening of the endometrium associated with uterine fibroids and showed that removal of the fibroids, when justifiable, was the only trustworthy means of arresting the endometrial thickening. Hence such thickening was probably inflammatory in origin. Dr. Briggs then mentioned several obstinate cases of metrorrhagia. In one Dr. Murray Cairns, the medical attendant, and the patient, aged 40 years, both pleaded for removal of the uterus, and the operation was eventually carried out. In some of the other cases the patients had had the uterus curetted three times by the indications for the abdominal over the vaginal route in the operation for myoma. Among recent methods for hysterectomy those *adopted by Zweifel, with his forci-pressure clamp*, and Bumm, with Kocher's forceps, were demonstrated. A differentiation of the advantages of the Alexander-Adams, Olshausen's, ventro-suspension and ventro-fixation modes of dealing with retro-deviations was entered into, as affecting the child-bearing period of life. The advantage of performing vaginal ovariotomy for cystoma was questioned, and the choice of abdominal and vaginal cœliotomy in diseases of the adnexa, as influenced by bi-section of the uterus, was considered, with the conditions of complications which gave to colpotomy the preference over vaginal cœliotomy. The justification for an occasional danger in the performance of conservative operations on the adnexa was discussed, and then the four vital points in relation to hysterectomy for carcinoma were touched upon—namely, early pan-hysterectomy, the demarcation between operable and inoperable cases, the best operation when disease had extended outside the uterus (Wertheim's operation was here described), and lastly, the alternatives to operation. The lecture closed with a retrospect of the position of gynæcology at present as compared with that of 22 years ago. All the matters touched upon in the lecture were illustrated by specimens bearing on the questions raised.

South-West London Medical Society.—A meeting of this society was held on Jan. 8th, Mr. John Gay, the President, being in the chair.—Dr. G. Herschell read a paper upon the Examination of the Stomach Contents as applicable to General Practice. After pointing out the small number of tests which were actually required and the facility with which they could be applied he demonstrated the following: the Congo-red test for free acid; Gunzberg's phloroglucin-vanillin test for free hydrochloric acid; the Topfer method of quantitative analysis of the gastric acids by titration with decinormal solution of sodium hydrate, using phenophthallein, alizarin, and dimethyl-amido-azo-benzol as indicators; the method of ascertaining the presence of rennin and rennin zymogen; and the estimation of the digestive power of the gastric juice by artificial digestion of white of egg; and he showed the successive changes of starch mucilage into erythro-dextrin-achroödextrin, maltose, and dextrin under the influence of ptyalin, and the reactions which were given at different stages with Lugol's and Fehling's solutions respectively. He concluded by exhibiting Turck's aspirator for obtaining gastric contents for analysis, Einhorn's intragastric spray and stomach bucket, Boardman Reed's intragastric electrode, Van Valsah's *stomach*-tube, and his own three-way-tap apparatus for washing out the stomach.—The paper was discussed by Dr. G. Richardson, Mr. C. R. C. Lyster, Dr. L. S. MacManus, and the President.—A hearty vote of thanks was awarded to Dr. Herschell for his paper.

Ipswich Clinical Society.—The annual meeting of this society was held on Jan. 9th.—The retiring President, Mr. J. F. C. Hossack, read a most interesting paper on Quakery and Charlatanism in their Relation to Modern Medicine.—The following officers were then elected by ballot:—President: Dr. G. Vincent. Vice-President: Mr. J. F. C. Hossack, Honorary secretary: Dr. W. A. Gibb. Council: Dr. H. H. Brown, Mr. Branford Edwards, Mr. C. K. Moseley, Mr. J. Staddon, Dr. Fowler Ward, and Dr. A. Paterson.—Dr. J. Purves Stewart was proposed, seconded, and unanimously elected an honorary member of the society.

Folkestone Medical Society.—The annual meeting of this society was held on Jan. 10th at the Burlington Hotel by invitation of the President, Dr. W. J. Tyson. After the annual report had been adopted Dr. C. E. Perry thanked Dr. Tyson for his services to the society as its President during the past three years.—Dr. T. Eastes was then unanimously elected President, Dr. J. Hackney and Dr. Tyson Vice-presidents, and Dr. E. G. Sworder honorary secretary and treasurer.—A musical programme concluded the meeting.

Pathological Society of Manchester.—A meeting of this society was held on Jan. 15th, Mr. J. Collier, the President, being in the chair.—Dr. A. Donald mentioned a case of *Unruptured* Tubal Pregnancy, and showed the specimen.—Dr. Donald and Dr. W. E. Fothergill showed Microscopical Sections from a case of Folliculoma Ovarii Malignum, and made a short communication.—Dr. F. C. Moore described Changes in the Pancreas observed in Diabetes Mellitus, and showed specimens.—Dr. P. Prebble exhibited Salivary and other Calculi.—Mr. Wolstenholme exhibited Sections of a large Aneurysm and Thrombus of a Branch of the Anterior Mesenteric Artery from a young horse, the condition having been produced by the irritation set up by wandering nematodes—immature sclerostomata equina (strongylus armatus). A number of specimens of the parasite taken from the lesion were shown.

## Reviews and Notices of Books.

*Impressions of a Doctor in Khaki.* By Francis E. Fremantle, M.A., M.B., *B.Ch. Oxon.*, M.R.C.P. *Lond.*, late Civil Surgeon to H.M. Forces in South Africa. London: John Murray. 1901. Pp. 549. Price 10*s.* 6*d.* net.

We have read this book with much interest, for its author saw a great deal in South Africa and has consequently a good deal to tell and he tells it well—that is, in a fresh and natural way. It falls to the lot of very few to have had such a field of observation and to have encountered such a varied experience within the same limits of time and opportunity. Under such circumstances it was well worth while to preserve and to publish a record of the author's impressions which are always more or less interesting and suggestive and sometimes valuable and instructive. With much of what is said we quite agree, but we confess, nevertheless, to have laid down the book with a somewhat mixed feeling regarding what he has to say about the army medical department and its officers. Notwithstanding the remarks of the author in his preface and those which he has here and there interspersed in the pages of his book in their defence against the criticisms to which they have been subjected the tone adopted by him is, on the whole, one of disparagement of the medical service and its officers. Every community, it is needless to say, has its good, bad, and indifferent members, and we can only suppose that the author had the bad luck at the outset of his army experience to have come across some undesirable or uncongenial individuals who either fell below his professional standard or ran counter to his views. It may be, after all, that combatant officers at the front in referring to "the medical department in terms of unstinted praise" (page 390) knew something of what they were talking about; and that the medical "system," despite all its real and alleged drawbacks and shortcomings, could not have been as bad as has been represented if the two "German army-doctors" who had "done four weeks' work at De Aar and the front, where they helped personally in the work of the field hospitals" could have been so "very favourably impressed with it" (page 130). These German medical *attachés* were, it may be assumed, well qualified to speak on the point. The system, by the way, is, in principle, much the same as their own which they saw put to the test in the Franco-Prussian war, but which had never before been applied under such conditions and circumstances as obtained in South Africa, because these were unique, and that being so made all the difference in the world. There are many medical officers of experience who think that it is in an increased development of our present medical and hospital system (with some modifications to adapt it better to the diverse and varying conditions of war) rather than in any radical change of that system that the best results are to be hoped for. As regards the maintenance of professional efficiency we have always advocated that increased opportunities and facilities should be given to medical officers in this respect and that greater chances of reward and distinction should be held out to such of them as showed any high professional or scientific merits. The Army nerves were uninjured, but a hole was present in the brachial artery plugged up by clot. Ligatures were placed over the torn ends as well as over the superior profunda branch and the ends were cut off. There was never any interference with the circulation in the arm. 2. A girl after second operation (excision) for Plexiform Angioma of the Scalp. At the preliminary operation the feeding arteries of the cirsoid aneurysm were ligatured. Electrolysis subsequently applied had little or no effect in reducing the pulsation—in fact, on her return to the hospital the pulsation was greater than it was before. A horseshoe-shaped incision with its base in front was made round the tumour. Mr. Stiles had great difficulty in dissecting out the vessels and the hæmorrhage was very great. The application of peroxide of hydrogen stopped the bleeding from the small vessels, while sutures around the edge controlled the larger ones. The wound healed well and now there was merely the scar of the operation present.

Dr. **WILLIAM ELDER** showed a man the whole of whose Thoracic and Abdominal Viscera were Transposed; the sigmoid flexure was digitally proved to be on the right side The man was perfectly healthy.

Dr. **C. W. MACGILLIVRAY** exhibited a girl, aged four and a half years, on whom he had operated for Obstruction of the Bowels with Suppurating Tuberculous Retro-peritoneal Glands Since the age of one year she had been subject to attacks of abdominal pain. Complete obstruction of the bowels commenced on Nov. 27th last with fæcal vomiting. When admitted to the Edinburgh Royal Infirmary on Dec. 3rd she was very collapsed and the abdomen was greatly distended in the middle line. On opening the abdomen the small intestine was found to be bound down by fibrous bands one and a half inches from the ileo-cæcal valve. These bands were divided and ligatured, when the intestinal contents immediately passed into the large intestine. Behind the constriction was an irregular lump, of the size of a Tangerine orange, composed of suppurating tuberculous glands which was removed.

Dr. **W. LESLIE MACKENZIE** demonstrated a simple form of Spray Pump for Disinfection. He had designed it to meet the case of small towns and hospitals for which the regulation spray was too expensive and too large. It was merely a gardening syringe with a properly adapted nozzle on a long arm and connected by bicycle indiarubber tubing to a force pump. The whole apparatus weighed only eight pounds, was easily disjointed, and so could be carried on a bicycle by the sanitary inspector. A three-nozzle piece could also be attached. To reach very high ceilings the tubing could be lengthened and the nozzle could be attached to the top of a Japanese fishing-rod.

Dr. **D. CHALMERS WATSON** exhibited photographs from a case of Cerebral Thrombosis in a Horse (unconscious for 24 hours) followed by complete recovery.

Mr. **STILES** showed as card specimens: (1) A portion of the Brachial Artery from the boy whom he had shown; and (2) a large Congenital Strangulated Cyst, weighing one and three-quarter pounds, which he had removed, together with six inches of small intestine, from a child, aged one year and eight months, who was suffering from acute intestinal obstruction.

Dr. **ALEXANDER BRUCE** showed a Transverse Section of Aortic Aneurysm

Mr. **J. M. COTTERILL** exhibited: (1) A Fœtus and Sac successfully removed in a case of Intra-peritoneal Rupture of a Tubal Gestation; (2) an Aneurysm of the Posterior Ulnar Recurrent Artery; (3) Semilunar Cartilages taken from a series of cases of Internal Derangement of the Knee-joint; (4) Parts removed in a case of Fracture of the Sternum with Dislocation of the Spine; and (5) a Kidney removed from a patient suffering from Profuse Hæmaturia.

Dr. **MACGILLIVRAY** showed a large Papilloma of the Rectum.

Dr. **GEORGE A. GIBSON** and Dr. **STEWART MCDONALD** showed: (1) A Spinal Cord showing Pseudo-Tabes Syphilitica, with a microscopical demonstration; and (2) Hæmorrhage into the Cusps of the Pulmonary Valve, with microscopical sections.

Mr. **C. W. CATHCART** gave a demonstration on an Adaptation by Dr. Ramsay Smith of the Freezing Microtome for Tropical Climates and of his rapid method of mounting permanent microscopical sections of fresh tumours. The three features which Mr. Cathcart thought specially to deserve attention were: 1. The adaptation of the freezing method of cutting microscopical sections to tropical climates. This was attained by embedding the tissues in cork and spraying ethyl chloride directly on to the tissue. Mr. Cathcart found that his ether spray used in this way did as well as ethyl chloride in a room with a temperature of 60° F. and was much cheaper. 2. The method of cutting, which consisted of a continuous raising of the screw with the left hand simultaneously with a rapid to-and-fro movement of the knife with the right, no attempt being made to adapt the screw at each cut. This was not only rapid but it gave exceedingly good sections, although the exact measurement of them was not attempted. 3 The method of mounting permanently sections of fresh tissues. This consisted in floating out the sections in from 2 to 4 per cent. of formalin after being cut, then floating on to a slide and staining with hæmatoxylin or eosin, dehydrating with absolute alcohol, and mounting in Canada balsam. Dr. Ramsay Smith found that he could cut sections at the rate of from 300 to 400 per minute and prepare and complete a stained permanent preparation within six or seven minutes after receiving the fresh tissue from the body or from the operating theatre. Mr. Cathcart referred the members for complete details of the method to Dr. Ramsay Smith's paper in the January issue of the *Scottish Medical and Surgical Journal.*

Dr. **ELDER** and Mr. **ALEXANDER MILES** contributed a paper on a successful case of Removal of a Tumour from the Left Prefrontal Lobe of the Brain.—In the discussion which followed Dr. **BYROM BRAMWELL**, after congratulating Dr. Elder and Mr. Miles on the successful issue of the case, said that his experience confirmed that of Dr. Elder that very few cerebral tumours were benefited by operation. He himself remembered only one successful case in many which had been operated upon. The chief interest of the paper lay in the points of symptomatology and diagnosis Three years ago he had recorded 11 cases of frontal tumour in which there was no doubt of the diagnosis. In seven of these there were well-marked mental symptoms, while in four there were none. Amongst other symptoms which he had noted in these cases were mental enfeeblement, loss of the power of attention, irritability, incoherence, delusions of suspicion, &c. It was difficult to say how far the symptoms were due to the tumour in the prefrontal lobe or to the pressure and other causes affecting other parts of the brain. Lesions diffused over the cortex might produce absolutely similar symptoms to those caused by a prefrontal tumour. He thought that it was not possible to draw a distinction between some cases of general paralysis and frontal tumour and he described a case to illustrate these difficulties in diagnosis. They had to depend more on the physical signs than on the mental symptoms in order to arrive at a trustworthy diagnosis of prefrontal tumour.—Dr. **EDWIN BRAMWELL** said that pain in the back was a very frequent concomitant of cerebral tumour, so much so that he invariably inquired into this symptom in investigating cases of cerebral tumour.—Dr. **ALEXANDER BRUCE** referred to the distinct degeneration of the posterior nerve-roots seen in many cases of cerebral tumour. The question was whether the nerve-endings were irritated by the accumulation of cerebro-spinal fluid. The pressure on the nerve-roots might give this appearance and might also account for the apparently meaningless sensory disturbances. He referred also to the difficulty in diagnosis between prefrontal tumour and general paralysis.—Mr. **COTTERILL**, Dr. **LOGAN TURNER**, and Dr. **H. M. CHURCH** also spoke.—Dr. **ELDER**, in reply, said that they were very apt to have a blurring of the symptoms on account of the pressure. He had noted that some symptoms were more marked than might have been expected and that some cases of general paralysis had symptoms specially referable to the frontal lobes, and in such cases it was found that the disease had affected these lobes to a special degree.

---

**CORK MEDICAL AND SURGICAL SOCIETY.**—A meeting of this society was held on Jan. 13th, Dr. T. G. Atkins, the President, being in the chair.—Dr. McNaughton Jones (London) delivered an address on the Critical Analysis of Some Recent Gynæcological Methods. Having discussed the conditions essential for an ideal asepsis the most recent methods of preparing the patient, especially those adopted by Professor Sanger and Professor Bumm at Prague and Halle respectively, were described. The advantage of colletin as a dressing and of bronze aluminium wire or celloidinzwirn as non-absorbable materials for skin-closure was shown. The conditions under which preference should be given to myomectomy over pan-hysterectomy and the question of removal of the ovaries were discussed, as well as ases, but it fails if the pylorus itself is ulcerated. It acts y providing free drainage.

The complications of gastric ulcer are very numerous; n this work we find a table containing 23 complications. One of the most important of these is hæmorrhage. Formerly it was often stated that "bleeding from the stomach the result of ulceration rarely proves fatal," but this opinion can hardly be held now. Surgical aid is required in most of the more severe forms and definitely after two severe hæmorrhages, for "experience tells us that further hæmorrhages are almost certain to occur unless preventive measures be adopted." The authors give a very good account of the technique of the operation for gastric hæmorrhage. In this connexion we may mention a very rare condition—namely, post-operative hæmatemesis. The authors point out that it occurs after operations for intestinal obstruction, tuberculous peritonitis, herniotomy, ovariotomy, and operations on the gall-bladder. Yet it is difficult to say to what it is due. Sepsis appears unlikely and the anæsthetic cannot be the cause as it has occurred when cocaine has been used. General treatment seems best for this condition, while the only two cases treated surgically by Reichard terminated fatally. The other important complication of gastric ulcer is perforation The differential diagnosis in such cases here is often easy, as a history of previous gastric ulcer can be obtained in 92 per cent; a case, however, is quoted in which there was a history of pain after food, but the symptoms which simulated perforation of a gastric ulcer were due to rupture of an ectopic gestation.

Perforation of a gastric ulcer demands immediate surgical treatment After the ulcer has been sutured the peritoneal cavity has to be cleansed. The authors prefer flushing with sterile salt solution at 105° F, and they say that it should be continued until the fluid returns clear. The several peritoneal pouches need especial care If, however, general septic peritonitis has developed, one or more free incisions may be ade, and the intestinal coils are then withdrawn sufficiently allow the operator to cleanse all recesses and folds with um salt solution and gauze pledgets. In 20 per cent. two cers are present; therefore, after one ulcer has been found others should be looked for.

We are glad to see that attention is drawn to the importance of the bacteriology of the extravasated material. Only by differences in the organisms present can we account for many of the great differences in course which are met with.

The authors consider that the prognosis after perforation depends on four factors: (1) the condition of the stomach, whether full or empty; (2) the time elapsing between perforation and operation; (3) the size and number of the perforations; and (4) the presence or absence and the severity of the vomiting. As to the results, without doubt successful cases are much more likely to be recorded than those which end fatally, and therefore too much stress must not be laid on the statistics.

Probably the oldest operation on the stomach is gastrostomy, which the writers tell us was first suggested by Egeberg, a Norwegian military surgeon, in 1837, but it was really first performed by Becher as long ago as 1635. The method specially preferred is Frank's, as modified by Mr. Mayo Robson. When the patient is much reduced in strength cocaine anæsthesia is quite sufficient. In all, the authors have performed 26 cases of gastrostomy with only five deaths.

Dilatation of the stomach from atony was until recently practically beyond treatment, either medical or surgical. Bircher, in 1890, reported three cases treated by gastroplication, and many others have since been performed. One of the authors, Mr. Moynihan, in 1898 described an ingenious method of gastroplication, and the results in the three cases in which the writers have employed it have been satisfactory.

There are many other matters dealt with in this volume which are of both interest and importance, but we think we have said enough to show the character of the work. It is eminently practical and should prove of value to all those, both physicians and surgeons, who are interested in the modern treatment of diseases of the stomach.

---

*Annual and Analytical Cyclopædia of Practical Medicine.* By CHARLES E. DE M. SAJOUS, M.D., and 100 Associate Editors. Illustrated with chromo-lithographs, engravings, and maps. Philadelphia, New York, and Chicago: F. A. Davis. 1901. Pp. 1043.

THIS volume forms the last of the first series of the present work. It contains subjects coming under the heading of titles commencing with the letters R to Z, or, to be more exact, from "Diseases of the Rectum" to "Zinc." The promises enumerated in the preface to the first volume of the series have been well fulfilled, as is proved by reference to the voluminous index given at the end of the present volume. The whole publication forms a mass of literature probably never before brought together within the limits of six books.

The work presents "all the general diseases usually described in text-books," in addition to the main progressive features which have been furnished by the past decade. Surgical subjects have been given space corresponding with their practical importance. As regards "therapeutics," the subjects considered represent the remedies still more or less used, our text-books being replete with agents which may be said to be obsolete from the fact that they have been replaced by others of far greater efficacy.

The present volume contains a large number of valuable articles, though we have not space to comment at length on any of them. Particularly valuable contributions are those on Diseases of the Stomach, by Professor D. D. Stewart of Philadelphia; on Diseases of the Spinal Cord, by Dr. W. B Pritchard of New York; on Syphilis, by Professor G. F. Lydston of Chicago; on Wounds and Injuries of the Chest, by Professor L. A. Stimson and Dr. E. L. Keyes, jun., of New York; and on Yellow Fever, by Surgeon-General Wyman of Washington. By the way, we cannot agree with Dr. Leveson of Copenhagen, who contributes a paper on Rheumatism, when he adopts "chronic articular rheumatism" and "rheumatoid arthritis" as synonymous terms.

---

## LIBRARY TABLE.

*A Manual of Minor Surgery and Bandaging for the Use of House Surgeons, Dressers, and Junior Practitioners.* By CHRISTOPHER HEATH, F.R C.S. Eng., LL.D. Montreal, Consulting Surgeon to University College Hospital, and Emeritus Professor of Clinical Surgery in University College, London. Twelfth edition. Revised by BILTON POLLARD, F.R C.S. Eng., Surgeon to University College Hospital and Teacher of Operative Surgery in University College, London. London: J. & A. Churchill. 1901. Pp. 426. Price 6*s.* 6*d.*—The many medical men who have learnt their bandaging and minor surgery from this little volume will feel no surprise at hearing that the work has reached a twelfth edition, for it thoroughly deserves such long-enduring success. Its clearness and accuracy are known to many generations of students. The old cause for fear when a book passes through many editions is that sufficient care may not have been taken to keep it up to date. In this case such fear is groundless, for Mr. Heath has entrusted to Mr. Bilton Pollard the task of preparing this edition and the work has been done well. The account of the methods of asepsis and antisepsis especially is good. We know of no book which is likely to prove more useful to a recently appointed house surgeon than this; it will be of assistance in many difficulties and may save him from many mistakes. The

Medical Service as at present constituted has little or nothing to offer in these directions. That this is so is no fault, however, of the medical officers.

Towards the conclusion of the volume the author, after putting forward a plan which would be nearly tantamount to doing away with an army medical department altogether, very strongly advocates the new scheme outlined by Mr. Brodrick's Committee, to which he acted as assistant secretary. We have no desire or intention to enter now upon controversial matters about which there exists, to say the least, much difference of opinion.

Dr. Fremantle went out to South Africa from Guy's Hospital and, as our readers probably know, some strictures of his which appeared in print attracted notice and gave rise to some temporary misunderstanding with the authorities. The subject is very fairly stated and referred to in this volume. After describing the voyage on his first going out in the *Roslin Castle* and his landing at Cape Town, he gives an account of his service at Wynberg, where he saw some of the wounded from Belmont, Graspan, and Magersfontein, followed by his being ordered home on the *Avoca* and of his subsequent return to South Africa. What happened to him there, together with his war experiences, professional and otherwise, at Bloemfontein, in the advance to Pretoria, and elsewhere, during his service at the front, is very well described and well worth reading. We may add that the volume has several excellent illustrations and maps, is printed in good type, and is easy and pleasant to read.

---

*A Treatise on Orthopædic Surgery.* By ROYAL WHITMAN, M.D., M.R.C.S. Eng., Instructor in Orthopædic Surgery and Chief of the Orthopædic Department of the Vanderbilt Clinic in the College of Physicians and Surgeons of Columbia University, &c. Illustrated with 447 Engravings. London: Henry Kimpton. 1901. Pp. 650. Price 25*s.* net.

ORTHOPÆDIC surgery has been for many years peculiarly indebted to the work of American surgeons, and it is due probably to that fact that so many books on orthopædics have issued recently from the press of the United States. The present volume is one of the most satisfactory works of the kind that have come before us; in it the subject is treated very systematically, numerous illustrations are provided to elucidate the text, and the treatment, which is discussed very fully, is reasonable and trustworthy.

The first chapter deals with tuberculous caries of the spine. This is probably the most important portion of orthopædic surgery. The consequences when the disease goes untreated cannot be surpassed in severity, while nowhere are the results more satisfactory when suitable and timely treatment is applied. An accurate knowledge of the very earliest signs is therefore of the first importance, and Dr. Whitman gives them exceedingly clearly. We may mention a useful method (new, at least, to us) of demonstrating unilateral contraction of the psoas in spinal caries. The child is placed on the back and the legs are allowed to hang over the edge of the table, when the unaffected thigh will drop below its fellow.

With regard to lateral curvature of the spine the author gives a very full account of the exercises which may be employed. We thoroughly agree with him as to the desirability of employing only exceptionally fixed supports for this condition.

Dr. Whitman thinks that in the treatment of congenital dislocation of the hip Lorenz's method will suffice for 25 per cent. of the patients; and should this method fail he considers that the "open" method may usefully follow and is rendered much simpler by the preceding attempts at forcible correction.

The author discusses the etiology of coxa vara; he does not believe it to be rachitic in origin; he considers that it is "one of the group of static deformities of the lower extremity caused by a disproportion between the strength of the supporting structure and the burden that is put upon it." This is, no doubt, true of many of the cases occurring in adolescence, but it will not serve to explain the cases which develop at an earlier age.

Some very valuable remarks on the correct shape of boots are given in connexion with acquired deformities of the foot.

Much more might be said, but it is unnecessary. We may, however, mention a useful feature. After many of the longer sections a summary is given of the chief points; these additions should prove of great value to readers.

---

*Diseases of the Stomach and their Surgical Treatment.* By A. W. MAYO ROBSON, F.R.C.S. Eng., Member of Council and Hunterian Professor (1897 and 1900), Royal College of Surgeons of England, Senior Surgeon to the General Infirmary at Leeds, Emeritus Professor of Surgery in the Yorkshire College of the Victoria University, &c.; and B. G. A. MOYNIHAN, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon, Leeds General Infirmary, Arris and Gale Lecturer (1899 and 1900), and Member of the Board of Examiners in Anatomy for the Fellowship, Royal College of Surgeons of England, &c. London: Baillière, Tindall, and Cox. 1901. Pp. 308. Price 15*s.* net.

IN 1900 Mr. Mayo Robson delivered the Hunterian Lectures at the Royal College of Surgeons of England on the Surgery of the Stomach, and this has formed the foundation on which this book has been built, though the two authors hold themselves "jointly responsible" for every statement in the book. As to the general results of gastric surgery we may quote from a statement in the preface that one of the writers has in his private clinic had only one death in the last 75 consecutive operations, and that death was from accidental perforation on the twelfth day, and the other has had a series of 47 hospital and private cases with only three deaths.

The conditions for which operations may be performed on the stomach are numerous, but some of them are of much greater importance than others. Perhaps gastric ulcer and its complications may be looked upon as the chief morbid state which demands surgical aid, and we find in this volume 120 pages devoted to this subject. The etiology of gastric ulcer has always formed a favourite subject for the formation of theories, but it cannot be said that any theory hitherto suggested explains satisfactorily the occurrence of this ulcer The prognosis of gastric ulcer is grave; according to Lebert death occurs in 10 per cent. of all ulcers—6½ per cent. from perforation and 3½ from hæmorrhage Habershon says that perforation occurs in 18 per cent. of all gastric ulcers, and Müller considers that the mortality from hæmorrhage is 11 per cent., but others give it as less. Even if we adopt the lowest figures of the death-rate from gastric ulcer we find it large, and if we agree with Brinton in putting the mortality at 50 per cent. the result is appalling. There is here evidently a large scope for the work of the surgeon, though of course the medicinal and dietetic treatment is of great importance.

The best operative treatment for a gastric ulcer which has not yet perforated can hardly be said to be settled. Excision is, as a rule, unnecessary, but in some cases of bleeding ulcers it cannot be avoided, and also where there is so much induration that a suspicion of malignant disease arises. Gastro-enterostomy is, the authors tell us, the operation to be relied on in the treatment of ulcer of the stomach; it gives physiological rest to the organ by drainage. They prefer the posterior operation, the hinder wall of the stomach being united to the first part of the jejunum. The posterior operation is preferred as it is less frequently followed by vomiting. Pyloroplasty is useful in certain familiar with the practical sides of the subject, including photography and electricity, recording their experience as to the best manner of operating and as to the most suitable and effective apparatus for the purpose. The book will be found very useful by medical men.

## JOURNALS AND MAGAZINES.

*The Practitioner.*—An adequate series of articles upon Hypertrophy and Dilatation of the Heart forms the bulk of the *Practitioner* for January. The subject is fairly conclusively discussed by the various articles taken *en masse*, but, as must inevitably happen when several writers are engaged upon the same subject in the same journal without an opportunity presumably of seeing each other's contributions beforehand, there is a tiresome amount of repetition. Professor T. C. Allbutt's article is admirable both in matter and, as is always the case with this writer, in the manner of putting it forward. Such discourses repay perusal for their style even if they give no novel information. In this case the writer speaks, as does Dr. William Collier of Oxford, from a position of peculiar advantage upon the question of heart strain and athletics. Professor Allbutt's opinion leans strongly to the view that exercise, pure and simple, rarely damages the heart, and that toxic influences, such as those from tobacco and alcohol, are the enemies to be avoided with the greatest diligence. In contrast to Professor Allbutt's view is that of Dr. I. Burney Yeo who states that "it is now quite common to meet conditions of grave cardiac strain from excess of muscular efforts in athletic contests." Professor Allbutt, however, is himself severely critical of excessive athletics for young boys, and gives an interesting instance of the evil effects that may arise. Readers will expect to find in these articles a careful consideration of the Nauheim treatment and they will not be disappointed. The class of case in which exercises and baths are to be recommended or withheld is discussed particularly by Dr. Burney Yeo and Dr. Richard Caton. Dr. A. E. Sansom contributes an interesting but diffuse article on Recent Study and Treatment as regards Hypertrophy and Dilatation. The medico-literary causerie consists of a comprehensive historical review of quackery.

# Analytical Records
FROM
# THE LANCET LABORATORY.

### (1) "TABLOID" HYDRARG. PERCHLOR., GR. $\frac{1}{16}$TH, ET POTASS. IODID., GR. 5; AND (2) "ENULE" MORPHINE AND BELLADONNA.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

IN those cases in which the continued administration of mercury with iodide of potassium is required the "tabloid" containing exact quantities of these salts is useful. We find that this tabloid dissolves readily in water and we are able to state that the salts are present in the precise amounts indicated. The tabloids are serviceable when regularity of treatment is important. A new formula has recently been added to the list of "enule" rectal suppositories of this firm: morphine hydrochloride, $\frac{1}{4}$ gr., and extract of belladonna, $\frac{1}{2}$ gr. The enule consists of a hermetically-sealed sheath of pure tinfoil which effectually protects the contents from deterioration or from outside contamination. The combination is, of course, sedative and anodyne, on which account it is useful in irritable conditions of the rectum.

### PLASMON BUTTER.

(INTERNATIONAL PLASMON, LIMITED, 66A, FARRINGDON-STREET, LONDON, E.C.)

The admixture of plasmon with butter must be regarded as a sound physiological procedure, since both are important nourishing constituents of normal milk. The mixture so obtained has also the advantage of possessing a very attractive taste. When plasmon—that is to say, the unaltered proteid of milk—is added to butter in a special way it endows it with a rich creamy flavour not unlike the flavour of Devonshire clotted cream. In appearance also plasmon butter resembles clotted cream. We have examined both plasmon butter and the ordinary butter used for making the mixture. The following are the results of the analysis: plasmon butter moisture, 41·20 per cent.; butter fat, 51·50 per cent.; dry plasmon, 6 58 per cent.; salt 0·72 per cent.; ordinary butter mixed with plasmon—moisture. 9 92 per cent.; fat, 87·71 per cent.; curd, 1·76 per cent.; and salt, 0 61 per cent. The addition of a proteid (identically in the same condition chemically and physiologically as in milk) to butter affords undoubtedly a valuable dietetic combination, and more especially for invalid purposes in which powerful nutritives are indicated. The Plasmon is introduced in the form of jelly. About 15 per cent. of Plasmon jelly is added to the butter. Plasmon butter is pleasant to take and should prove an excellent substitute for cod-liver oil. It contains both a proteid and a fat of a highly assimilable character, each of which, moreover, favours the nutritive processes. We have received also a copy of the Plasmon Cookery-book, containing a great number of recipes in which Plasmon is employed with undoubted dietetic advantages. Directions for preparing a great variety of dishes are given.

### CARICA COCOA.

(PUCKA COFFEE CO., 30, GALLOWAY-STREET, MAXWELLTOWN, DUMFRIES.)

The distinguishing feature of this cocoa is that it contains a vegetable enzyme and on this account the preparation is regarded as being of an easily digestible character. It is difficult to see how the cocoa can be favourably modified by the addition of a digestive ferment the activity of which is destroyed by boiling water. If an infusion of this cocoa were first maintained at blood temperature for some time before cooking some digestive action would probably take place. The cocoa used is of excellent quality and flavour and has evidently undergone some special preparation, as the amount of mineral matter is excessive and the alkalinity is decidedly high. Our analysis gave the following results: moisture, 4·63 per cent.; mineral matter, 8·66 per cent.; fat, 31·95 per cent.; and non-nitrogenous proteid and fibre, 54·76 per cent. The alkalinity of the mineral matter was equivalent to 2·8 per cent. of potash (calculated as $K_2O$).

### AQUARIUS WATER SOFTENER.

(THE LONDON AND GENERAL WATER PURIFYING CO., 157, STRAND, LONDON, W.C.)

We find by analysis that the ingredient of this powder is well adapted for the purpose of rendering hard water soft. The addition of the powder, however, only removes the hardness due to carbonate of lime dissolved in carbonic acid gas and not that which may be due to sulphate of magnesium or of calcium. In short, the addition of the powder removes temporary hardness to the same degree as would continual boiling. The powder, however, is very convenient for the purpose. Used in the proportions indicated it would do no harm, adding nothing to the soluble constituents of the water and eliminating the chief source of hardness.

### "BISPEP."

(MUNDY, MAHONY, AND CO., 36, PARADISE-STREET, BIRMINGHAM.)

The formula of this preparation is very well known. It contains aromatics, bismuth, and ammonia carbonate, pepsin, present edition is fully worthy of those which have preceded it.

*A Practical Treatise on Genito-Urinary and Venereal Diseases and Syphilis.* By ROBERT W. TAYLOR, A.M., M.D., Clinical Professor of Venereal Diseases at the College of Physicians and Surgeons (Columbia University), New York; Surgeon to Bellevue Hospital, &c. Second edition, thoroughly revised, with 138 Illustrations and 27 Plates in Colours and Monotone. London: Henry Kimpton. 1901. Pp. 722. Price 25s.—It is a little difficult to see why the title of this work apparently excludes syphilis from being a venereal disease; probably the intention is merely to draw attention to the fact that syphilis is included in the volume. The work has, the author tells us, been written to occupy a position midway between an encyclopædia and an epitome, and we think that Dr. Taylor has been successful. The book is quite abreast of the present-day knowledge of these important subjects, and the treatment is sufficiently full to enable a medical man to carry it out satisfactorily, while no space has been wasted on the description of obsolete methods. This is a decided gain, for the number of methods now employed is so large that no time can be devoted to processes which have been rejected as useless or unsatisfactory. The account of gonorrhœa and its complications is especially good, and we thoroughly agree with the author's description of many of the methods of treating gonorrhœa as "fads." He points out that most of these methods which are supposed to "abort" gonorrhœa in five or 10 days leave an infectious mucous discharge. The illustrations are good, especially those which are coloured. We consider that this new edition can be confidently recommended as complete and trustworthy.

*Photographic Atlas of the Diseases of the Skin: a Series of 80 Plates, comprising more than 100 Illustrations, with Descriptive Text, and a Treatise on Cutaneous Therapeutics.* By GEORGE HENRY FOX, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, New York, &c. In 12 parts. Parts V. to XII. Philadelphia and London: J. B. Lippincott Company. 1901. Price 6s. each part.—We have already expressed a very favourable opinion on the first four parts of this work, and the succeeding eight parts are equally satisfactory. They will form, when the issue is complete, an excellent atlas of cutaneous disease. The chief objection to the photographic representation of skin diseases is the tendency for the reds to come out black on account of the small actinic power of red light. In these plates this difficulty has been in great measure obviated and the results are very good indeed. The text and the remarks on treatment are all that could be desired.

*Études de Clinique Chirurgicale.* Par le Dr. ANTOINE PACHECO MENDES, Professeur de Clinique Chirurgicale à la Faculté de Médecine de Bahia. Avec 26 figures dans le texte dont 4 en couleur. Paris: Librarie Médicale O. Berthier. 1901. Pp 200.—There is a fairly well-known school of medicine at Bahia—in fact, it may be said to be one of the chief medical schools of South America; but in this country comparatively little is heard of the work done there, and this must be attributed chiefly to the fact that Portuguese is very little known here. The volume before us is written in French and therefore appeals to a larger circle of readers. Dr. Mendes has put together a number of interesting observations which he has made in his clinic, and he tells us that he hopes to publish another volume when he has accumulated a sufficiency of new material. There are 22 sections in the book and each deals with a single subject. We may mention a few of the more important. The first is on the Employment of Sulphur in Local Tuberculosis. The author expresses himself as very well pleased with this substance when used after scraping, and he draws especial attention to the little likelihood of return of the disease when sulphur is employed. He cites many cases in which the use of sulphur was followed by recovery, but he utters a warning that the application of sulphur is by no means painless. A valuable article is concerned with Aneurysm of the Gluteal Artery. It contains a table of 50 cases which the author has collected. In some of the cases, however, the aneurysm appears to have been connected with the sciatic artery. Dr. Mendes is in favour of extirpation of aneurysms, not merely in the gluteal region, but wherever situated. The author also describes a method of removing hæmorrhoids which is not absolutely new, but has been very little used. It consists in dissecting up the mucous membrane from the pedicle of the hæmorrhoid, tying the pedicle with catgut, then fashioning two small flaps from the mucous membrane, removing the pile and suturing the flaps together. Every one of the subjects discussed is treated in a novel manner and we may look upon this little book as a distinct contribution to surgical literature.

*Essentials of Gynæcology* (Arranged in the Form of Questions and Answers). By E. B. CRAGIN, M.D., and FRANK S. MATHEWS, M.D. Fifth edition, thoroughly revised. With 57 Illustrations. London: Henry Kimpton. 1901. Pp. 207. Price 4s. net.—This volume, of the series known as "Kimpton's Student's Essentials," should be of some value to the students of gynæcology. The book is in no sense to be considered as complete, but is intended to assist the student in a review and summary of work done. It has reached a fifth edition and we may conclude is bought and used. For such men as are unable to attend the excellent tutorial classes now held in all large hospitals the book will, no doubt, prove valuable, and, indeed, it may prove suggestive even to the teacher of such classes in providing him with a number of suggestive elementary questions.

*A Manual of Obstetrics.* By A. F. KING, M.D. Eighth edition, revised and enlarged. With 264 Illustrations. London: Henry Kimpton. 1901. Demy 8vo. Pp. 612. Price 12s. 6d net.—We need say but little about a book which has reached its eighth edition, since this fact alone is sufficient to demonstrate its excellence. As only two years have elapsed since the appearance of the last edition of Dr. King's "Manual of Obstetrics" very slight alteration has been required. The chief addition consists of 41 new illustrations which have been selected from the works of American authors. Although, as the author points out, the book remains elementary, no attempt having been made to develop it into a systematic text-book, yet it is steadily growing in size The present edition contains 612 pages, as compared with 574 pages in the last edition. The book is, on the whole, well up to date, and we can recommend it as a good example of an elementary manual of obstetric medicine.

*Practical Radiography.* By A. W. ISENTHAL, F.R.P.S., and H. SNOWDEN WARD, F.R.P.S. Third Edition. Published for the Photogram, Limited, by Dawbarn and Ward, Limited, 6, Farringdon-avenue, London, E.C. 1901. Pp 198. Price 6s —This is a well-printed and well-illustrated book which may be placed in the hands of the beginner in x-ray work with confidence. The authors have dealt with their subject in a very methodical way, beginning with a historical review of the subject and finishing with a short and authoritative account of the new fields of research which have been opened up by Roentgen's remarkable discovery. The wonderful phenomena of radio-activity, manifested by certain elements and amongst them some entirely new ones, is described. In general, however, the book will serve best as a practical guide, the apparatus and accessories being clearly described. It is evident that the writers are perfectly

THE LANCET.

*LONDON: SATURDAY, JANUARY 25, 1902.*

## First Aid and Hæmorrhage.

A LETTER which appeared in THE LANCET of Jan. 4th (p. 54), written by Mr. W. G. SPENCER, raises a very important point. Mr. SPENCER states that the teaching at ambulance classes with regard to the arrest of hæmorrhage appears to result in impressing upon the minds of the pupils that in any case of hæmorrhage some sort of improvised tourniquet must be applied above the bleeding-point and that the value of direct pressure is not recognised. He quotes sundry instances to show that owing to this method of procedure even death has occurred in circumstances where life ought to have been preserved.

First-aid classes have undoubtedly done much valuable work and probably many a simple fracture has been kept from conversion into a compound fracture by the application of first-aid measures for procuring temporary immobility. But although the lectures may be sound, yet many of the hearers are, after having been taught, afraid to exercise their common-sense. In many books which have been published upon first-aid and ambulance work the directions for the arrest of hæmorrhage are classified under those appropriate for arterial, venous, and capillary hæmorrhage. For the last class pressure over the wound is always advised; but for the first two pressure above or below the wound is insisted upon as the main treatment, while pressure over the wound is relegated to a secondary position. In books classification is presumably necessary, yet in practice a wound sufficient to cause alarming hæmorrhage is rarely to be included in only one of the above categories. The commonest example of a wound producing only one kind of hæmorrhage is a wound of a varicose vein in the leg. In this class direct pressure is assuredly indicated, because when a varicose vein gives way the hæmorrhage comes both from the proximal and the distal portion of the vessel—in fact, much more from the proximal than from the distal. The common forms of severe cuts, which as a rule affect the fingers, hands, or arms, produce capillary and venous hæmorrhage, although in the fingers a digital artery may be divided, or in the wrist the ulnar or radial artery, but in both cases the superficial veins and the venæ comites are divided also. Severe punctured wounds, if they divide a deep-seated artery, almost invariably sever or puncture the vein as well, a condition of things which again demands the application of direct pressure

To solve the problem of the correct treatment of hæmorrhage we must go back to general surgical principles. In the first place we must distinguish the hæmorrhage after wounds of vessels in their continuity from that due to the complete removal of a part of a limb. In the latter case there is no room for doubt that a firmly applied tourniquet is the only method of rapidly controlling the extensive hæmorrhage which is generally present. But far otherwise is it with a wound of a vessel, whether artery or vein, in its continuity. In all surgery the simplest means that are efficient should have the preference. The pressure of a finger can control the hæmorrhage from any vessel in the body if the pressure be applied at the wounded spot. That the pressure should be applied at the wound in the vessel has been a fixed principle of surgery for very many years. And not the temporary means only for arresting the hæmorrhage, but the permanent means also act with most certainty when applied at the wound in the vessel. Neglect of this rule has led to many errors. That it is possible to control the blood-flow from a wounded artery by the application of a tourniquet higher up is undoubtedly true, and when carefully applied the tourniquet is of great value during any operative procedures which may be undertaken. But if a tourniquet is carelessly or ignorantly applied it is certainly capable of leading to loss of far more blood than it saves. As a tourniquet is being applied (and we are speaking of improvised tourniquets and not of some special instrument) its first effect is to arrest the flow of blood in the veins at the point of application, because the blood-pressure in the veins is very much less than is the blood-pressure in the arteries As the blood-flow in the arteries is not yet arrested, the normal quantity of blood will enter the limb, but hardly any can leave it by the veins, therefore the hæmorrhage will be much more profuse than if no tourniquet had been applied. As the pressure exerted by the tourniquet increases it is able to compress the arteries somewhat so that the quantity of blood entering the limb is diminished, but still no blood can leave the limb by the natural channels, and therefore still the amount of blood lost is greater than it would otherwise be. It is only when the instrument compresses the arteries that hæmorrhage from the wound ceases. Now, the pressure required to compress an artery if applied directly to the vessel is by no means great, but when the pressure is exerted by constricting the whole limb it needs to be very much greater, and it is probable that the requisite degree of pressure is very seldom attained by amateur efforts, even though the operator is well instructed in ambulance work. As to the instruction which should be given to an ambulance class there can be no doubt. For all ordinary wounds hæmorrhage is best controlled by direct pressure on the wounded spot; the finger is the simplest and handiest means of applying pressure and should be used until a pad can be prepared and applied. If the pad controls the hæmorrhage well and good, if not the pressure of the finger on the spot should be resumed.

We have little fault to find with the instructions for the arrest of hæmorrhage laid down in the manual issued by the St. John Ambulance Association. The only suggestion that we would make is that it would be well to simplify the directions. As they stand they are too numerous and too elaborate to be called readily to mind in the excitement of an accident. It is impossible to train the average students of an ambulance class to act as skilled surgeons in a moment of emergency; the most we can expect is to instruct them so that they may, by the application of a few simple rules, avert immediate death or unnecessary increase of the danger of the accident.

&c. Its action, therefore, combines that of an antacid, carminative, and anti-fermentative. We recognise no particular merit about this preparation. It would undoubtedly be of service in some cases while in others it might easily be contra-indicated. Its indiscriminate use, therefore, is to be condemned, and the words on the label describing the list of ailments it is said to remove are highly exaggerated and misleading.

### LOMBARDY BUTTER.

(F. CORTI AND CO., 45, GERRARD STREET, LONDON, W.)

A feature of this butter is the small percentage of water which it contains, the question of the amount of water in butter being very much in evidence just now. It is proposed to fix a limit, and we believe that the consensus of opinion is in favour of 16 per cent. of water as a maximum amount. As our analysis shows, this specimen of Lombardy butter contains not more than three-fourths of this proportion. On the large scale there is no difficulty in producing butter containing less than 15 per cent. of water, but in isolated instances (as in the case of a small farmer) the reduction of water to this limit is not so simple We found the Lombardy butter of good quality and flavour. It yielded results characteristic of butters of known purity. Thus it yielded a maximum proportion of volatile fatty acids, a high Reichert figure being obtained, The Valenta test also gave a satisfactory result. Further analytical results were as follows: water, 12 86 per cent.; butter fat, 85 83 per cent ; curd, 1 21 per cent, ; and salt, 0 01 per cent. A small addition of borax has been made.

### VYTALLE OIL.

(THE VYTALLE OIL CO., LIMITED, 465, BATTERSEA PARK ROAD, LONDON, S W )

Vytalle. Oil is a clear yellow oil, limpid at ordinary temperatures. It possesses a bland flavour suggesting a very mild butter. It is described as a mixture of pure vegetable oils. From our examination and the physical constants which we obtained olive oil would appear to be the predominating constituent. Thus the Valenta test gave 79° C. as the point of interfusion, while the Maumêne test gave a temperature of 49° C The specific gravity of the oil at normal temperature was 0 917 From the fact, as we found, that the oil is very readily saponified it may be concluded that it is easily assimilated and there is, therefore, some ground for urging its claims as a substitute for cod-liver oil. It is not unpleasant to take and it does not give rise to disagreeable eructations.

### "ANTIFIÈVRES" (ROBERT).

(AGENCY. GILBERT KIMPTON AND CO., 19, ST. DUNSTAN'S HILL, LONDON, E C )

This preparation is described as a radical cure for fever. It is a strongly acid brown fluid with a disagreeable smell resembling in part sour beer and in part chicory infusion. No definite chemical principles could be identified. It contained neither quinine nor arsenic. There was some alcohol present. The fluid yielded 5 63 per cent. of syrupy extract and 0 74 per cent. of mineral salts, consisting principally of alkaline salts corresponding in nature with those commonly yielded by vegetable extracts We have not been able to find any satisfactory clinical evidence respecting this "radical cure."

### (1) BANANA MALTED FOOD (BOYD); (2) PINE HOP-BITTERS (BOYD); AND (3) ANTISEPTIC EAU-DE-COLOGNE (BOYD).

(MEDICAL AND GENERAL SPECIALITIES CO., 300, CLAPHAM ROAD, LONDON, S W.)

Odd as it may appear, the banana malted food consists chiefly of cooked wheat-flour according to our microscopic examinations. The food is rich in phosphates, a fact which would account for the total mineral matter reaching as high a figure as 2 per cent. The preparation contains a good proportion of proteids, carbohydrates, and phosphatic constituents in well-planned ratio, and the method of manufacture is calculated to render these elements easily assimilable. Pine hop-bitters is a somewhat curious compound, containing, amongst other things, the fresh juice of the pineapple, cinchonidine, and sodium persulphate. This sodium salt is said to be a powerful stimulant to the appetite, and on this account might be given to tuberculous patients. Sodium persulphate certainly acts as an anti-fermentative and has been employed in the treatment of hyper-acidity. Antiseptic eau-de-cologne contains a well-known but somewhat irritating germicide. It is stated also to contain peroxide of hydrogen but we could find none. We are not surprised at this result since peroxide of hydrogen is not compatible with a powerful reducing agent.

# Looking Back.

FROM

## THE LANCET, *SUNDAY, JAN.* 25, 1824.

What I would do if I had strangulated hernia would be this, I would have the taxis employed steadily for ten or fifteen minutes, if this did not succeed, I would be bled to syncope, and then have the reduction by the hand attempted again; if this also proved unsuccessful, I would have the tobacco injection, and wait a short time; and then, if necessary, have the operation performed; it is the most egregious ignorance possible, to delay the operation so long as is often done, thereby wasting those precious moments which, if properly used, might have been spent in saving the life of the patient; ask those about our hospitals who are the persons who die from strangulated hernia! and they will tell you those who have the operation delayed three or four days, and are not brought to the hospital till three days after the hernia has been strangulated, and then if operated on, they often die: the delay is the cause of the danger, and not the operation. I have had a little personal experience of this complaint, and have devoted no small share of my attention to it, and I would not wait more than twelve hours, if the tobacco enema and other means had been employed. Now let me allude to the case of a late illustrious Nobleman, (I am almost afraid now to mention names—*laugh*), who died of this disease; he was in the country, and during his stay there, had strangulated hernia, he was attended by a person of strong mind, and who had studied his profession with industry; he offered to perform the operation, but it was delayed, on the ground that London skill and advice should be obtained; but before this could be had, the Nobleman died: I do not mean to under-value London skill, but it certainly is great folly to delay in this complaint. I would propose the operation, and perform it readily if it was agreed to; but if not, I would wash my hands of the affair, and be freed from the consequences.[*]

### ST. THOMAS'S HOSPITAL.

Jan. 23d. No operations have been performed here this week.

The accidents that have been admitted are a fracture of the patella, of the tibia and fibula, an injury to the hand, fracture of the ribs, and a burn.

---

[*] Excerpt from report of a lecture on hernia delivered by Sir Astley Cooper in the Theatre of St. Thomas's Hospital on Wednesday evening, Jan. 21st, 1824.

CONGRESS OF THE SANITARY INSTITUTE, MANCHESTER, SEPT. 9TH-13TH, 1902.—*President:* the Right Hon. the Earl Egerton of Tatton. Section I.—Sanitary Science and Preventive Medicine—will be presided over by Sir J. Crichton Browne, LL.D., F.R.S. Section II.—Engineering and Architecture—will be presided over by Sir Alexander Binnie, M. Inst. C E. Section III.—Physics, Chemistry, and Biology—will be presided over by Professor A. Sheridan Delépine, M.B , C.M., B Sc. Eight technical conferences will also be held in connexion with the congress.

men, and while possessing the necessary knowledge would be likely not to have quite the qualities that would make it easy for them to impart their knowledge effectively. In our opinion the proper channel for such instruction to the people is the popular press. The editors who will arrange regularly to instruct their less educated readers in the principles and practice of sanitary legislation will be engaged in a really beneficent work.

◆

# A Magistrate and Scientific Witnesses.

THE *Daily Telegraph*, in its report of a case heard before Mr. SHEIL at the Westminster Police-court, records certain observations of the learned magistrate to which we venture to take exception. The prosecution was for adulteration under the Sale of Food and Drugs Act, and Mr. SHEIL had been informed that some technical objection was to be taken to the analyst's certificate. Presumably this objection was not upon a point of law, for it seems to have provoked the following remarkable outburst, which is apparently given verbatim :—"Mr. SHEIL: Of course, you can get as many experts on either side as you like by paying their fees. (Laughter.) Any number of learned scientific gentlemen will swear one thing, and an equal number of learned scientific gentlemen retained on the other side will swear to the contrary. (Laughter.)" These observations had, as will be seen, the effect much desired by so many of those who sit on the judgment-seat in this country of raising a laugh among the audience that loves to hang about law courts, and to the full approval of his "gallery" Mr. SHEIL is no doubt entitled. He is not, however, entitled to approval from those who do not desire to see the proceedings in a court of law interrupted by cheap sneers at members of learned professions—at gentlemen, that is, whose aid is invoked by lawyers in order that truth may be arrived at in difficult inquiries. That scientific witnesses frequently differ from one another everyone knows. Let us take a simple instance more or less of everyday occurrence The surgeon who is called in to attend upon a man who has been injured by the negligence of another, and who afterwards supports his patient's claim for damages, expects to find that a surgeon representing the negligent defendant may take a less gloomy view than himself of the duration of the victim's symptoms. One surgeon is in court to inform the jury of the term during which the defendant may be incapacitated, the other is there to point out his chances of early recovery; and after both have been cross-examined the jury is expected to decide the question—to whose evidence should most weight be attached? In cases that are heard at police-courts witnesses on different sides may differ in opinion as to the amount, for example, of boric preservative that may be added to an article of diet without injury to the consumer. Each witness will be genuinely convinced of the accuracy of his own view and may from his own point of view be entitled to have weight attached to his opinion, but the questions upon which he has given his testimony are questions to a large extent of opinion, and his answers are given as opinions and nothing more upon a topic with regard to which no one can speak with certainty. And if these questions of opinion are regarded as questions of fact it must be remembered that upon simple questions of fact, such as the identity of a person or the time at which an event happened, mistakes are frequently made by witnesses who are neither learned nor scientific and of whose good faith there can be no question. We recommend Mr. SHEIL on the next occasion upon which he is inclined to level discourteous taunts at the head of members of learned professions and callings to recall the days when he was a practising member of a learned profession himself. He will remember that lawyers belong to the profession which of all others permits its members to take a side for hire. We do not sneer at the legal profession—we recognise that advocacy is the *raison d'être* of many of its members; but we remind Mr. SHEIL that when he talks glibly of the experts of science we are entitled to ask—What about the experts of the law? We take it that in some cases at all events that come to the law courts for decision the litigant who is destined to meet defeat has been strongly advised by eminent and perfectly honest counsel before he embarked in litigation that his claim or his defence was a sound one. Or should we say in turn that "any number of learned legal gentlemen will advise one thing and an equal number of learned legal gentlemen retained on the other side will advise to the contrary"? We have no desire or intention to make any statement that would be both discourteous and untrue. It will be remembered also that we do not assert that scientific witnesses never differ in their evidence and never allow themselves to be influenced by prejudice. It is against the sweeping charge of wholesale flagrant venality and perjury that we protest.

◆

# The Isolation of Small-pox Patients.

THE spread of small-pox or any other infectious disease which demands the isolation of patients for the benefit of the community necessitates a careful study of the Acts under which local authorities are entitled to order the removal of sufferers from their homes. A proper appreciation of the rights and duties of the local authority is necessary both from the point of view of the medical officer of health and the medical practitioner and from the standpoint of the public. Forcible removal of a suspected patient to a hospital ship unless carried out by sanction of law might give rise to an action for false imprisonment; it will be well therefore to remind our readers of the law upon the subject in so far as the interests of medical officers of health and private practitioners are affected, indicating the scope of their duties, and in what way they are protected from liability in their private capacities.

The text of Section 124 of the Public Health Act, 1875, which may be regarded as the leading statutory enactment dealing with this important matter, reads as follows :—

"Where any suitable hospital or place for the reception of the sick is provided within the district of a local authority, or within a convenient distance of such district, any person who is suffering from any dangerous infectious disorder, and is without proper lodging or accommodation, or lodged in a room occupied by more than one family, or is on board any ship or vessel, may, on a certificate signed by a legally qualified medical *practitioner, and with the consent of the* superintending body of such hospital or place, be removed by order of any justice to such hospital or place, at the cost of

No one could have a higher opinion of the value of first-aid than we have, for we are sure that it may be the means of saving many limbs and even many lives, but the instruction must be given with a due appreciation of the intelligence and knowledge of the learners. This, as some of the correspondence called forth by Mr. SPENCER's letter—notably Mr. HAMILTON WHITEFORD's communication—shows, the Manual of the St. John Ambulance Association does not always allow for.

# The Public Health Act and the Spread of Disease.

It would seem that the number of persons who while suffering from an infectious disease do not scruple to mingle with the general public or who allow persons under their charge to commit the same serious offence, is increasing. Within the last three months many offences of this kind have come prominently under our notice, only a few of which we have been able to record. At any time such a state of things would be alarming, but while an epidemic of small-pox is raging alarm must be necessarily increased. It is true that such offences have been provided for in the Public Health Act, but some of our magistrates do not seem to comprehend the gravity of the offences. For example, a fine of 2*s* 6*d*. only was exacted recently from a woman who exposed her child while suffering from scarlet fever, and 10*s*. in each case was the penalty that another woman had to pay for exposing her infectious child on two occasions, though the magistrate remarked that the exposure had probably been the means of infecting other persons. On Oct. 15th, 1901, in the East-end of London, it was mentioned at an inquest[1] that seven persons in one family in one house were suffering from small-pox without being medically treated, and that one of the family, a lad, on being told to remain in the house until the medical officer of health had been sent for to confirm the diagnosis of small-pox, had left the house and gone to work in a coal-yard The coroner incidentally remarked at the same inquest[2] that a woman had that day been found drunk in the streets while suffering from small-pox. Many striking instances of persons engaging in every-day occupations while suffering from infectious diseases, and especially from small-pox, have since been brought to our notice. The offender is sometimes ignorant of the fact that he is infectious, but that is another question. This is not at all usual and accounts for a very small percentage of the cases where the public health is endangered by the exposure of infectious persons. That the greatest watchfulness on the part of sanitary authorities is necessary is well illustrated by the outbreak of small-pox at Ystalyfera in South Wales. The patient who conveyed the infection from London is believed to have travelled from London to Swansea by train and from that place, again by train, to Ystalyfera. She must necessarily have come under the observation of many officials, none of whom seem to have detected that there was anything suspicious in her plight.

We cannot therefore wonder at the spread of disease in spite of the most strenuous efforts of medical officers of health and sanitary reformers. Nor do the ridiculously small fines imposed by magistrates on offenders against the law tend to improve matters. Ignorance of the law is no excuse in the eye of the law, though ignorance and poverty may sometimes account for the smallness of the fines imposed. The sections of the Public Health Act of 1891 in dealing with the matter state that: "If any person while suffering from any dangerous infectious disease wilfully exposes himself without proper precautions against spreading the said disease in any street, public place, shop, or inn; or, being in charge of any person so suffering, so exposes such sufferer; or gives, lends, sells, transmits, removes, or exposes without previous disinfection any bedding, clothing, or other articles which have been exposed to infection from any such disease, he shall be liable to a fine not exceeding £5." In the case of a person knowing himself to be suffering from a dangerous infectious disease engaged in any occupation in a manner likely to spread the disease the maximum penalty is £10, and the same maximum penalty applies to the driver of a public conveyance who knowingly conveys a passenger suffering from an infectious disease and also to the person being so conveyed if he himself is aware of the fact that he is so suffering Where poverty and ignorance are factors in the case magistrates may perhaps be forgiven for erring on the side of leniency, but where, as in a recent case, a man can afford to travel the whole length of England, while suffering from scarlet fever, to escape from the jurisdiction of the sanitary authorities, a fine of 40*s*. is hardly adequate. Nothing but the severest punishment will ever prevent such selfish people from defying the law. With regard to offenders who belong to the poorer classes something, we think, might be done if more publicity were given not only to the Act but to the consequences of violation of the law in regard to health

A common motive which prompts the poor to conceal disease is a pecuniary one, for sickness in their homes may mean nothing less than loss of employ for the bread-winners, be they wives, husbands or children. But the poorer classes are more susceptible to reason than we often give them credit for, and if in some way the position could be made clear to them much benefit both to them and to the general public might follow. Force is, perhaps, necessary to carry out the law for the general good in certain cases, but blind obedience without a reason is not a trait in the Englishman's character whatever place on the social ladder he may occupy, and the experiment of educating the poor in matters which affect the public health by teaching them the reason of sanitary orders and laws might well be given a trial. How this could best be effected other than by the publication of handbills and public notices is a matter for consideration. A suggestion has been made to us that senior medical students should visit the poor and in temporal matters impart to them a certain amount of instruction akin to that which it is the province of the minister to give in a spiritual capacity? There is point in the suggestion, but we fear that the number of senior medical students willing to give the time and dowered with the proper amount of tact and sympathy is not very large. Medical students are young quickly complied with, while some of those who most objected to removal to hospital have, on the termination of their illness, expressed their gratitude for the benefits that they had received in hospital.

# Annotations.

"Ne quid nimis."

## THE FAILURE OF INSULATION AND ITS PERILS.

It is idle to dispute the advantages and convenience of electricity for lighting purposes and as a source of motive power when it can be shown that the actuating current can be kept well under control. Electricity, however, is evidently not an easy force to harness, judging from the extraordinary and alarming crop of accidents which have occurred quite recently in connexion with several electric railways. Accidents of this kind in closely fitting tubes suggest such awful possibilities that, naturally enough, public confidence in this mode of travelling has been considerably disturbed. Nor is the alarm thus created calculated to be allayed by the invariable explanation that the occurrence is due to "short-circuiting." It would be more satisfactory if the public could be assured that short-circuiting can be prevented. If it can be prevented, why is it not done? or is it a contingency against which it is not possible to provide with certainty? In that case cannot steps be taken to safeguard the travelling public against the serious effects of short-circuiting? Short-circuiting, it must be admitted, arises from a defect in the insulation which may or may not have originally existed, but in the great number of instances doubtless it is the result of, perhaps unforeseen, rapid wear and tear. Until, however, some better guarantee is forthcoming than has hitherto been the case that the most effective measures are taken to prevent short-circuiting or to obviate any serious consequences when it is established, travelling on an electric railway, and especially in the "tubes" in which there is practi[illegible]y only room for the train, means running a risk of a [illegible]re never heard of before in connexion with railways. [illegible] accidents arising from short-circuiting in Liverpool, [illegible]ew York, and on two of the London "tubes" are cases in point. We, of course, are aware that accidents are bound to arise in connexion with rapid travelling which cannot be reasonably anticipated In the case of ordinary railways the snapping of a rod or coupling, or the bursting of a steam-pipe, belongs to this class. But in regard to electric railways it is demonstrated again and again that almost always the cause of accident is the failure of insulation. The explanation of the defect is simple, but explanation does not appear to afford a way out of the evil, and until such a way is found all sense of security vanishes. The same defect has led to outbreak of fire in the dwelling-house. It is appalling to think of the ease with which an insidious glow can be established in the casings and beneath the floor. The current taking a short route, the wires heat up and, as often as not, the woodwork or carpet bursts into flame We have had personal experience of such occurrences, and it seems to us that greater control is required in regard to the way in which installations are fitted up in private houses. We cannot think that the electrical engineer will admit that he is baffled by such a defect, the exact nature and cause of which he perfectly well knows We also think it desirable that the electric-supply companies should issue to their customers a few elementary hints on the handling and management of the current for domestic purposes. Very few people understand what a "cut out" or safety fuse is and still less its function Much needless alarm would be spared the householder if he could be made to understand a little about these things. As it is, he looks upon electricity as a mysterious force which is easily provoked to do mischief. Should anything occur (however slightly abnormal it may be), perhaps a weird fizzing noise, or the "implosion" of a lamp, or the sudden, intense illumination of the filament through leakage somewhere, he is invaded with a species of terror and is powerless to act, being afraid that he is on the eve of a disaster nothing short of electrocution. His fears are intensified by the accounts which he remembers reading of horses being killed suddenly by walking upon the lid of an electric box in the street—and such instances are known and they are not entirely rare, being due once again to the failure of insulation. Once more we ask, Cannot the failure of insulation be prevented?

## FOOD-SELLERS AND THE LAW.

THREE convictions obtained in the London police-courts during a single week illustrate the dangers which beset the humbler classes of the community and the extraordinary effrontery with which the adulteration of food is carried on in spite of the efforts made to check it. They will also to some extent, we hope, serve as a warning to those who endeavour to grow rich by imposing on their neighbours In one a Suffolk farmer was fined £10, with £3 3*s*. costs, for depositing for sale at the Central Meat Market the carcass of a pig with regard to which Dr. W. Collingridge, medical officer of health of the City of London, was of opinion that it had died from acute tuberculosis. It may not have actually drawn its last breath without the intervention of the butcher, but the man who stated that he was employed to kill it and who certainly prepared it for sale and forwarded it to London gave evidence and admitted that the hearts, livers, and lungs of this animal and another were given to the dogs, although the carcases were considered good enough for the food of human beings in the metropolis. We are pleased to note that the expenses of the obliging butcher as a witness were disallowed by the magistrate. An inspector of the West Suffolk police informed the court that the defendant in this case was chairman of the local School Board and a guardian of the poor. In the second prosecution which we have noted Frank Ward, carrying on business at Sidmouth-street, Hackney, was convicted of selling as "butter" at 1*s*. a pound stuff composed to the extent of 94 per cent. of cotton-seed oil. Mr. Ward pleaded in extenuation that it was his first offence, or rather his first conviction, and if it proves to be his last the penalty of £10 with two guineas costs and the alternative of a month in gaol will not have been exacted in vain. The third case to which we call attention seems to show that a difficulty may arise in the minds of some magistrates where the legislature orders them to punish those who sell goods not of the nature, substance, and quality of those demanded by the purchaser, and leaves it to their good sense to determine what is or is not of that nature, substance, and quality, without laying down a definite standard or analysis for their guidance A woman keeping a small grocer's shop in Southwark was summoned under the Food and Drugs Act for selling as golden syrup a compound which, indeed, contained 15 per cent. of cane sugar, but of which the residuary 85 per cent, was starch glucose. Mr. Paul Taylor at the first hearing of this case adjourned it, apparently in order to consider whether in the absence of any standard or legal definition of "golden syrup" he could convict, and finally he only imposed a nominal penalty of 5*s* with 12*s* 6*d*. costs. This leniency may have been prompted by pity for the ignorance of the retail trader, but if light punishment is to be the reward of the shopkeeper who professes ignorance he will have but little temptation to inquire the local authority, and any person so suffering who is lodged in any common lodging house, may, with the like consent and on a like certificate, be so removed by the order of the local authority

"An order under this section may be addressed to such constable or officer of the local authority as the justice or local authority making the same may think expedient, and any person who wilfully disobeys or obstructs the execution of such order shall be liable to a penalty not exceeding £10"

The powers conferred upon local authorities by this section were extended by Section 4 of the Canal Boats Act, 1877, to any sanitary authority within whose district a canal or any part of a canal may be situate in order to permit the removal of infectious cases from canal boats The section was also extended to ships by the Public Health (Ships, &c ) Act, 1885, Section 2 and Schedule It will be seen that in substance this Section 124 confers a power of removal upon local authorities acting in accordance with the certificate of a medical practitioner when the infected person — (1) is without proper lodging or accommodation, or (2) is lodged in a room occupied by more than one family; or (3) is on board a ship or canal boat, or (4) is in a common lodging house

The responsibility of the certifying practitioner becomes apparent when it is pointed out that the determination of what is "proper lodging or accommodation" rests with him In deciding this question he is apparently entitled to take into consideration the danger of infection to others In the case of WARWICK v GRAHAM,[1] the facts were that the respondent's son was suffering from scarlet fever at his father's house where a family of eight persons, including the patient, resided The house contained four rooms The patient occupied one room and had proper lodging and accommodation so far as he himself was concerned, but he could not be sufficiently isolated to prevent danger of infection to other inmates of the house who had to pass the door of the sick room The patient was properly cared for The medical officer made a certificate under the Public Health Act for the removal of the patient, but the justices refused to make an order on the ground that there was not sufficient evidence to show that the patient was without proper lodging and accommodation within the meaning of the section It was decided by the Divisional Court (DAY and LAWRANCE, JJ) that the section was directed to the protection of persons from infection and not merely to the protection of the sick person himself, and the case was sent back to the justices to make the proper order The learned judges here followed the cases of BOOKER v TAYLOR[2] and REG v DAVEY[3] In the latter case Mr Justice DARLING said "The legislature means to protect the public from infectious diseases If persons can obstruct and delay the operation of the order the whole purpose of the legislation may be defeated" Mr Justice CHANNELL expressed the view that the justices were wrong in thinking that they could go behind the order

It is thus clear that the certifying practitioner, who is usually the medical officer of health, has power to order the removal of rich and poor alike, if he thinks that course advisable in the interest of those living in the neighbourhood In cases where extreme measures have to be adopted owing to the opposition of the patient's friends the medical officer of health will do well to take a second opinion as to the nature of the disease from which the patient is suffering It is obvious that in legal proceedings which might be brought by a patient removed *vi et armis* from his home as the result of mistaken diagnosis the case for the defence would be materially strengthened by independent testimony So long, however, as the medical officer of health acts in strict accordance with the provisions of the 124th Section of the Public Health Act, 1875, he will be protected from legal proceedings by Section 265 of that statute which provides (*inter alia*) that "No matter or thing done by any local authority or joint board or port sanitary authority, and no matter or thing done by any officer of such authority or other person whomsoever acting under the direction of such authority, shall, if the matter or thing were done *bona fide* for the purpose of executing this Act, subject them, or any of them personally to any action, liability, claim, order, and whatsoever, and any expense incurred by any such authority, member, officer, or other person acting as last aforesaid, shall be borne and repaid out of the fund or rate applicable by such authority to the general purpose of this Act" Strict adherence to the very letter of the law is therefore essential In the Scotch case of MITCHELL v the MAYOR OF ABERDEEN[4] an action was brought against a medical officer who had directed the removal of a child suffering from an infectious disease without an order of justices, as required by Section 42 of the Public Health (Scotland) Act, 1867, which corresponds to Section 128 of the English Act He was held liable in damages, the court declaring that he was not entitled to the protection afforded by Section 118 of the same Act, which is identical in terms with Section 265 of the Act of 1875 above quoted. It seems that the words used in the Public Health Act, 1875 are quite wide enough to protect any private practitioner who acts with the sanction, and in pursuance of the orders of, the local authority

So much for the legal right of the local authority, acting by their medical officer, to direct the forcible removal of an infectious patient Those who are doubtful about the expediency of having recourse to extreme measures may be to some extent relieved by a study of the "General Report upon the Use and Influence of Hospitals for Infectious Diseases," which was presented in 1882 to both Houses of Parliament, and which was re issued in 1894 The late Sir RICHARD THORNE there made the following observations upon the working of the 124th Section of the Public Health Act, 1875 —

> "One result of the inquiry has been to show how seldom such compulsory measures have been resorted to, the cases brought under my notice amounting in all to not more than some three dozen at the outside In several instances, however, where persuasion has failed, either certain preliminary steps have been taken to procure a magistrate s order or the order itself has been obtained with a view of proving that the sanitary authority had the power in certain cases of resorting to compulsion, and in the majority of districts one such exhibition of power has sufficed to obviate any further resort to it."

Sir RICHARD THORNE also pointed out that when once an order had been obtained it was in nearly every instance gradually disappeared. The extremities were constantly cold. The temperature fell slowly to normal on the fourth day and was subsequently subnormal, reaching 95·5° in the rectum on the evening before death which took place on the eighth day of the illness. There was alternately constipation and diarrhœa, and 48 hours before death and 27 hours after the suppression of urine blood-colouring matter and broken-down blood cells were constantly in the fæces, which previously were blood-stained only occasionally. The heart began to fail on the fourth day. The skin became more and more jaundiced. On the fifth day after admission mucous casts were passed. Examination of the blood showed destruction of the red corpuscles which finally were reduced to 1,166,000 per cubic millimetre, while the leucocytes were 66,450 and the nucleated red cells 22,150. The alkalinity of the blood was diminished by 80 per cent. At the necropsy acute nephritis and intestinal catarrh were found, but nothing to account for the melæna.

## THE CHEMISTRY OF NERVE DEGENERATION.

WE desire to call the attention of all neurologists, and of those specially interested in the treatment of insanity, to a paper by Dr. F. W. Mott and Dr. W. D. Halliburton published in the Philosophical Transactions, Series B, vol. cxciv., pp. 437–466. The title of the paper is "The Chemistry of Nerve Degeneration" and it well merits study, not only as a model of the way in which researches of this kind should be conducted, but also because the writers draw conclusions of considerable practical value in the diagnosis of nervous disorders. The keystone of the paper is the importance of excess of choline in the blood in cases of nerve degeneration, not only in diseases such as general paralysis, but in various diseases of the central and peripheral nervous system. The detection of choline, which is a product of the decomposition of lecithin, is effected by a chemical test, the obtaining of the yellow octahedral crystals from the blood, and also by a physiological test—viz, a temporary fall of pressure when injected intravenously in animals. The degenerated nerves in the animals were examined by the Marchi reaction which consists of a mixture of osmic acid and Müller's fluid by which the degenerated nerve-fibres are stained an intense black, whilst the healthy fibres are not stained. We do not propose to follow the writers in their various experiments. It is enough to say that the whole subject is clearly and scientifically worked out and that it forms a very valuable addition to our present knowledge of the chemistry of the blood in disease. There is good reason for saying that these valuable experiments were suggested by work previously done by Dr. Mott in the post-mortem rooms of the London County Asylums, and we take this opportunity of asking why the appointment of a special pathologist is confined to the asylums under the jurisdiction of the London County Asylums. We should like to see the experiment extended to the asylums under the control of the Metropolitan Asylums Board. At the imbecile asylums there is a profusion of material which is completely thrown away, and material of the most valuable kind, for among the weak-minded degenerates who form the bulk of the population of these district asylums are examples of disease set up in more elementary conditions than are met with in the county asylums, and in these undeveloped types there may be found clues to the unravelling of the more complicated structure of better developed brains, and lesions of a congenital kind which may better elucidate the true nature of physiological as well as pathological processes. So far the District Asylums Board has not made any move in this direction; it has carried out, more or less completely, its function of housing and maintaining a certain number of imbecile and demented people, and it may think that in doing this it has fulfilled its office. But we say very decidedly that its duty is not completed with this performance. It is surely part of the obligation of a great body to see that nothing should be lost of the material which it has at its disposal to further ends which may eventually be of the greatest advantage to the people generally and to the insane population in particular. The patients of these district asylums are very cheaply maintained, and certainly the medical element does not figure largely in the expenses. It may be sufficient for carrying on the care and treatment of the patients, but to do more than this is out of the question, the medical staff have not the time to devote to laborious scientific investigation, and the appointment of a pathologist who could work on the lines so successfully inaugurated by Dr. Mott would, we feel sure, be a welcome addition to the efforts that are now being made in London to place the teaching and the investigation of insanity on a proper basis. Is it not somewhat of an anomaly that the administration of lunacy in London should be under two distinct boards each independent of the other? The time seems to have arrived when the whole lunacy system should be fused into one body, more especially as there are in the district asylums many patients who are actually suffering from chronic insanity, as distinguished from mere imbecility, and who were at one time under the protection of the Lunacy Laws. For instance, what a convenience would result, to say nothing of an economy, from having the maintenance, the administration, the distribution, and the classification in the hands of one authority. The system would not be too large and it would be quite practical to work the strings from one centre. Moreover, convenience would ensue from the possibility of interdigitating one class of building with another in the matter of classification and treatment, what an opportunity for the correct compilation of results and statistics and for the creation of a harmonised system where at present there is confusion. The Asylums Board may be very well left with the management of the infectious hospitals, work to which it has risen in a most praiseworthy manner, but it can well afford to delegate its functions in a part of the lunacy question to the County Council, and we think that the latter would willingly embrace the opportunity for a consolidation of these scattered units. It is true that the district asylums were constituted in 1870 by a special Act introduced by Mr. Gathorne Hardy, and most probably some fresh legislation might be necessary before the care of the imbeciles could be transferred to another body by the one to which it was first committed, but in view of the great advantage which would result from what we are now recommending no difficulty need be apprehended on the legal score. The subject of the best form of accommodation for the treatment of patients connected with London is still occupying the earnest thought of the County Council, and the various proposals for the erection of "receiving houses," of a special building for the complete treatment of acute cases in London, and of other improvements are still *sub judice*. Before final arrangements are made it is to be hoped that the advisability of incorporating the existing separate units will be carefully considered.

## THE TRAINING OF STATE CHILDREN.

HOW to provide for the training and maintenance of destitute children is a question which has occupied the minds of local authorities and of public-spirited philanthropists for more than one generation. It has given rise to a variety of schemes for its solution, which, nevertheless, if we are to judge from the practice of boards of guardians, remains to be found. The divergence of opinion which is thus indicated is most regrettable both from an economic and from a social standpoint. We seem to have as yet no into the quality of the goods that he sells. Exemplary punishment, on the other hand, warns him and others that the retail trader should be, in relation to his customers, an expert who can and must protect them against deception. Beyond this we should hardly have thought that "golden syrup" needed definition. Those persons, not being entirely ignorant, who ask for "golden syrup" know that, roughly speaking, it is a by-product of sugar, and that sugar is derived from sugar-cane or beetroot by processes into which they do not inquire. The entirely ignorant expect to get "golden syrup" such as their parents gave them when they were young, or such as they have been in the habit of consuming, and neither the well-informed nor the ignorant ask for starch glucose at their grocers'. If they did ask for it by name—an exceedingly unlikely contingency—they would be entitled to have it, and if it was sold to them diluted with the product of the sugar-cane or the beetroot the vendor would be liable to prosecution under the Food and Drugs Act for selling that which was not of the nature, substance, and quality of the goods demanded. A standard definition of what ordinary beer should contain was not required in order to enable magistrates to convict under the Sale of Food and Drugs Act persons who sold beer containing appreciable quantities of arsenic, the presence of which, by the way, was accounted for by the use of glucose in brewing. It is, no doubt, possible to draw up definitions of the elements that all articles of diet should contain, in anticipation of the ingenuity that may be exercised by ingenious traders in diluting them, but it would not be easy to make such a list complete, and the case of the beer referred to, which was argued before the High Court on appeal, has shown that it is not necessary from a legal point of view. We observe that Mr. Paul Taylor is reported, in giving his decision, to have said that he supposed that there would be no objection to the sale of the compound described before him under the name of "treacle." Not being aware of the learned magistrate's reason for this remark, we can only say that in our opinion to sell starch glucose as treacle would be as objectionable as to sell it as golden syrup. The term "treacle" was originally, in accordance with its derivation, a medicinal term used for certain antidotes for the poisonous bites of wild beasts and snakes. Of its derivation and the meanings which it has borne in mediæval times those who ask for "treacle" in small grocers' shops are entirely ignorant. They are not in the position either of manufacturers who, we believe, distinguish by the terms "treacle," "golden syrup," and "molasses" fluid products obtained at different stages or by different processes when the sugar of commerce is being prepared. The persons who ask their grocers for treacle, golden syrup, or molasses all, in our opinion, mean the same thing, and they certainly do not mean or desire to have any such compound as that which has been described.

## SMALL-POX IN LONDON

THE Local Government Board has issued the following notice for the information of the public: "There is reason to believe that the spread of small-pox in London is very materially aided through the instrumentality of persons who, though not recognised as attacked by the disease, are nevertheless suffering from a modified form of it and are conveying its infection to others. The Local Government Board are advised that it is important that where persons, especially adults, develop what is supposed to be chicken-pox no time should be lost before authoritative medical opinion is obtained as to the nature of the malady, and that as respects anyone brought into relation with a case which is regarded as one of chicken-pox steps should at once be taken to obtain or renew that protection against small-pox which is afforded by vaccination. It is believed that many persons who have been recently revaccinated fail to submit themselves to medical inspection, as they should do, a few days after the operation, but assume from the appearance of the arm either *that the operation had been successful* or that they are insusceptible to small-pox. These assumptions, however, are not always correct, and it is highly important that all who are revaccinated, especially during the prevalence of small-pox, should be inspected by a qualified medical man." The returns for the week are slightly better as regards numbers. On Saturday, Jan. 18th, 22 fresh cases were notified and removed; on Sunday, the 19th, there were 25 fresh cases; *on Monday, the 20th, there were 37 fresh cases*; on Tuesday, the 21st, there were 26 fresh cases; and on Wednesday, the 22nd, there were 35 fresh cases. The City of Westminster has taken the very wise course of making chicken-pox a temporarily notifiable disease under Sections 55 and 56 of the Public Health (London) Act, 1891. The order of the Mayor, Aldermen, and Councillors comes into force to-day (Friday), the 24th. We think that this is a very sensible decision on the part of the City of Westminster and one calculated to lead to the diagnosis of many a case of small-pox which might very likely have passed unnoticed otherwise. We may add that Westminster makes the eighth borough in which chicken-pox must be notified, the others being Hampstead, St. Pancras, Hackney, Holborn, Bethnal Green, Greenwich, and Paddington. The Local Government Board has issued a circular to extra-metropolitan guardians calling to mind former circulars issued in February, 1893, and July, 1895. These circulars deal with small-pox in casual wards and workhouses. When such a case occurs measures should at once be taken to secure as far as practicable vaccination or revaccination of the other inmates.

## DEATH FROM TAKING 60 GRAINS OF ACETANILIDE

TOXIC symptoms have frequently followed the administration of acetanilide (antifebrin) even in medicinal doses, but cases of fatal poisoning must be very rare. One is described by Dr. Philip King Brown in the *American Journal of the Medical Sciences* for December. A man, aged 37 years, was given 60 grains of acetanilide in six powders for headache and he took them all within a few hours. When seen by his medical attendant (after what interval of time is not stated) he was slightly delirious and complained of pain in the head and in the left umbilical region. There were pyrexia, rapid heart, marked constipation, slight jaundice, nausea, and vomiting. Calomel in small doses followed by salts produced a copious but bloody motion and the urine was dark red. On the following day he was admitted to hospital. The pulse was 78, soft and compressible; the temperature was 100·2° F.; the lips and nails were extremely cyanotic; and there was slight jaundice. *He complained of pain in the left* side of the abdomen and there was tenderness in the epigastrium and in the region of the left kidney. The skin was moist and the gums were bluish. The urine was strongly alkaline and deep red—nearly black. The colour was shown to be due to hæmatoporphyrin. There was a small sediment which contained granular casts. On boiling a large coagulum formed. On the day after admission only 150 cubic centimetres of urine were passed; after this there was complete suppression. There was great thirst which was quenched with milk, but soon everything that was given was rejected and rectal feeding had to be adopted. Though nothing was given by the mouth for days the vomiting continued. Cough and expectoration were persistent. There was slight delirium and the reaction of the pupils to light became more and more sluggish; in the end the pupils were widely dilated. The reflexes were first exaggerated, then they of small-pox occurring in their respective districts. Copies of this information are at once sent to all the medical officers of health in the county of London, so that every medical officer is put in early possession of all available information as to cases occurring in other boroughs, which may affect his district. The London Government Bill of 1899 has thrown some difficulties in the way of health administration in the metropolis. For instance, the hospitals to which cases of infectious disease are removed are dissociated entirely from the disease-preventing authorities; but, considering the multiplicity of authorities dealing with public health matters throughout the county of London, we think that the said authorities are doing their best to ascertain and to identify cases of small-pox and to limit the spread of this very infectious complaint.

## THE MUNICIPAL INSPECTION OF LONDON RESTAURANTS.

A resolution was adopted by the London County Council at its meeting on Tuesday last, that the Public Health Committee of the Council should be asked to consider and to report as to the best means of exercising periodical inspections of the kitchens of public restaurants. The resolution called attention to the fact that in London there are many thousands of persons whose business compels them to have the greater part of their food in public restaurants and undoubtedly it is of material importance that such food should be prepared in wholesome and sanitary surroundings. The Public Health Committee, in devising machinery for carrying out effective methods of investigation, will keep before it the plans adopted in the official inspections of bakehouses and factories, and it is our belief that it will find in many eating-houses of the metropolis a state of things justifying the action of the Council many hundred times over.

## CRIME IN GENERAL PARALYSIS.

In the *Journal of Mental Science* for January Dr. W. C. Sullivan, deputy medical officer of H.M. Prison, Pentonville, has published an article on the medico-legally important subject of crime in general paralysis. While crime has been extensively investigated in recent years in association with conditions of arrested or distorted cerebral and physical development (criminal anthropology), less attention has been given to a class of criminals in whom the morbid aptitude for criminal acts is connected with acquired cerebral degeneration or defect, such as might be caused by alcoholic intemperance or general paralysis. The examination of conduct in chronic alcoholism shows a remarkable frequency of suicidal and homicidal impulse as well as a tendency to sexual crimes, a subject to which attention has already been called in these columns.[1] In general paralysis, on the other hand, says Dr. Sullivan, the character of conduct was entirely different. A rough illustration of this might be given in statistical form. During nine years (1888 to 1896) among convicted prisoners certified as insane in the local prisons of England and Wales there were 274 cases (261 males and 13 females) in which the form of mental disease was considered to be general paralysis. Amongst these 261 male general paralytics homicide or homicidal attempts constituted the crime in nine cases, suicidal attempts were met with in eight cases, sexual offences in 13 cases, assaults in 21 cases, crimes of acquisitiveness in 144 cases, threats in eight cases, and other offences in 58 cases. Crimes of acquisitiveness were notoriously common in general paralysis, their most typical form being petty larceny, fraud, forgery, and embezzlement. Generally the circumstances and execution of the offence showed a characteristic silliness, though occasionally the general paralytic did commit robbery or fraud with an appearance of adequate motive and premeditation. The most important point to be noted was that this tendency existed in the exalted and optimistic variety of general paralysis and not in the depressed or melancholic form. Very often the impulses to theft or undue acquisitiveness preceded the grandiose delusions by a long period of time or were met with in the purely demented type of general paralysis without delusions. Besides this impulsive origin, paralytics who had lost money or blundered in their accounts might in a more lucid phase embezzle to make good the deficit—a point of practical importance in relation to the question of legal responsibility. Paralytics are also very amenable through their *naïveté* to criminal suggestion by others. Magnan quotes the case of a patient who was sent by his wife to steal in the Bon Marché, and Foville mentions two instances where paralytics were used as tools to utter forgeries. Acts of violence may be committed by paralytics when their grandiose tendencies are opposed, but the majority of grave acts of violence depend on a primary homicidal impulse generated by the more or less persistent state of emotional depression. Sexual offences in early paralysis—in the form of rape, defilement of children, and offences against public decency—are not uncommonly met with.

## A CASE OF DENTAL DISEASE OF OBSCURE ORIGIN.

A case of disease of dental origin terminating fatally is recorded by Mr. E. W. Roughton in the last issue of the Transactions of the Odontological Society. The patient, a man, aged 36 years, complained of a swelling in the region of the left angle of the mandible. When seen by Mr. Roughton about two months after the onset of the trouble there was a large inflammatory swelling involving the region of the angle of the mandible and extending upwards on to the cheek, forwards to the submaxillary region, and backwards over the sterno-mastoid muscle. The gum in the region of the molars was swollen and the skin over the swelling was red and œdematous. Deep-seated suppuration was suspected, but there was marked absence of pain, tenderness, and fever. An incision into the swelling evacuated a little serum but no pus. Fomentations were then applied in the hope that the swelling would suppurate freely and then clear up. The reverse, however, occurred, for the swelling slowly but steadily increased in size and declined to suppurate. An exploratory incision was next made and two or three small pieces of necrosed bone were removed. A large quantity of soft, friable granulation tissue was found but there was no collection of pus. Subsequently a sequestrum about an inch square was removed and the mandible fractured spontaneously. The swelling gradually extended down the neck and displaced the trachea and larynx. The swelling in the neck was then freely incised, but still no collection of pus was discovered; some small pieces of dead bone were, however, removed. A bacteriological examination of the tissue was made and an almost pure culture of streptococcus pyogenes was obtained. There was no actinomyces. The condition of the patient became worse, the wounds in the neck assumed a phagedænic character and the skin between them sloughed, and death took place owing to the ulceration laying open the carotid artery. The post-mortem examination showed that the mandible on the left side was destroyed as far forward as the lateral incisor; the internal organs were healthy and there was no evidence of pyæmia. The case is of interest from many points of view. 1. The absence of pain from first to last. 2. The slight degree of fever. During the 10 weeks the patient was in hospital only twice did the certain standard of the average cost per child which ought fairly to be required for this work, nor have we apparently any well-defined ideal of what the result of training should be. One thing is not desired: it is not intended to leave the child of poverty in the grasp of those habits of mind which tend to pauperism. On the contrary, it is generally understood among those who have gone most deeply into the subject that there can be no real progress unless the whole course of education is inspired by those principles of self-reliance and social responsibility which govern the robust life of self-respecting communities. There is abundant proof to show that it is in vain to think of developing any such inspiration in children maintained together by the score and hundred, as they are in many great parochial charities. It is quite exceptional to find in the institution-bred child that healthy individuality which is characteristic of children who have been boarded out in the freer and more natural atmosphere of family life. Between these two extremes of social existence there are not a few intermediate systems, the cost of which and their influence upon character have been tested by a lengthy experience. We believe we are right in saying that success, whether economic or educational, varies in direct and fairly accurate ratio with the degree to which the practice of segregation has been carried. There are training ships, certified cottage-homes, facilities for boarding out and for emigration, all available for the orphaned or forsaken children of this country and, as a rule, they are found to justify the expectations founded on them. On the other hand, we find parishes like Woolwich, Greenwich, and Stepney expending large sums on the creation of so-called village communities, the very title of which is expressive of pauper aggregation with all its mischievous associations. It is inconceivable that two methods so contrary should produce similar results. And experience has proved that they do not.

## ASPHYXIA FROM PRESSURE ON THE CHEST.

IN the *Boston Medical and Surgical Journal* of Jan. 2nd Dr. H. L Burrell and Dr. L. Crandon have described a remarkable case of "Traumatic Apnœa or Asphyxia"—stoppage of respiration by pressure on the chest. This condition is well known as a cause of death, but it has been principally studied post mortem, because usually it is fatal in a few moments. Hence the value of a case of recovery such as the following. A man, aged 22 years, was caught between an electric car and a doorpost and his chest was compressed antero-posteriorly as in a vice for three minutes, then, when the car was moved, he fell unconscious. An hour later, when admitted to hospital, he was still unconscious. The pulse was 100 and weak but regular; the respirations were 30 and shallow. The hands and nose were cold. Blood flowed from the ears and the nostrils. The pupils were small and equal and did not react to light; there was great chemosis. The knee-jerks were absent and the other reflexes were diminished. There was a fracture of one or more of the left lower ribs but subcutaneous emphysema of the left chest anteriorly was an obstacle to examination. The most striking feature was a dusky, bluish, mottled appearance of the skin of the head, face, neck, and chest as low as the third rib. At first the patient was thought to be cyanosed, but the colour was not universal, did not disappear on pressure, and persisted after he improved. Uniformly distributed all over the dusky skin were minute areas (from 0 5 to 1 millimetre in diameter) of normal tint surrounded by ill-defined bluish borders which united into a meshwork. This condition extended over the lips to the mucous membrane of the mouth. There were considerable subconjunctival and minute retinal hæmorrhages The urine contained albumin and blood. Nitroglycerine $\frac{1}{25}$th of a grain; atropine, $\frac{1}{64}$th of a grain; and strychnine, $\frac{1}{25}$th of a grain were given subcutaneously. After four hours consciousness returned. On the fourth day the patient was comfortable but the livid colour was unchanged. On the ninth day the colour began to fade but it did not go through the modifications of an ecchymosis; on the twelfth day it had all but disappeared. The patient was discharged practically well in the fourth week. There are several historical examples of this accident—the rush of the mob at the Champs de Mars in 1837, when 23 persons were crushed to death; the panic at the Pont de la Concorde in 1866, when a mob crushed nine of its members to death; the fire at the Vienna Ring Theatre in 1881 with nearly 1000 fatalities; the panic at the Victoria Hall, Sunderland, when nearly 200 children were asphyxiated by being crushed in a corridor; and the charity bazaar fire in Paris in 1897. Dr. Ollivier, who examined the bodies of the victims of the Champs de Mars catastrophe, says that without exception the face and neck were of a uniform violet tint and spotted with ecchymoses. In nine persons there were subconjunctival extravasations, in four sero-sanguineous froth ran from the mouth and nose, in four blood flowed from the nose, and in three from the ears; and in seven there was fracture of ribs. In females the sternum was fractured The large veins were filled with blood and the vessels of the pia mater were engorged. There were effusions of blood into the posterior part of the lungs. In the Pont de la Concorde cases Tardieu found punctate hæmorrhages in the loose tissue of the pericranium, under the visceral pleura, and on the surfaces of the heart and abdominal viscera. The peculiar colour of the skin described above is explained by Dr. Ollivier as due to stasis of carbonised blood in dilated and paralysed capillaries. The indications for treatment are manifest. If the patient is seen immediately after the accident artificial respiration should be performed; later, stimulants should be used, as in the case related.

## THE CONTROL OF SMALL-POX IN AND AROUND THE METROPOLIS.

IN our issue of Jan. 18th (p. 175) we discussed the question as to what the new metropolitan borough councils and other authorities of London were doing with regard to controlling the spread of small-pox. We also mentioned that it was possible that some members of Parliament might be asking what the London County Council was doing with regard to small-pox; and we suggested that the enemies of the Council might hold that body lukewarm in regard to the prevention of small-pox. At the meeting of the County Council which was held on Jan. 21st Mr. G. J. Cooper, the chairman of the Public Health Committee, took THE LANCET very seriously to task, and is reported as saying that no better answer could be made to the article to which we have referred than the report which the Public Health Committee had presented. That report now lies before us and we can assure Mr. Cooper that its contents afford a complete answer to the hypothetical question which we put in our issue of last week. From this report we learn that common lodging-houses, in which a case of small-pox has occurred, have been constantly visited by the officers of the Council and that some slight pecuniary assistance has been given, owing to which the inmate of a common lodging-house, if ill, has been found to be willing to keep himself isolated in a particular room until he can be certified to be suffering from some malady which warrants his removal to an infectious diseases hospital. There is, of course, no power of compulsory vaccination, but the Public Health Committee believes that objections may be sometimes overcome by the offer of a small pecuniary consideration. The medical officer of the County Council has made an arrangement with each of the borough medical officers by which the latter supply him daily with all particulars which they have been able to ascertain with regard to each case gas used was equivalent to 33 grammes of cyanide to 100 cubic feet of space. Shelves were fixed across the window of the room, and on them the cages containing animals and insects were placed for easy examination. House flies exposed in the ordinary wire traps were killed in from two to four minutes after effervescence began in the cyanide jar. Bed-bugs were placed in tubes plugged with two inches of cotton, and these were put inside a Florence flask plugged with five inches of cotton. The bugs were therefore under seven inches of cotton. The room was closed in this experiment for 25 minutes, when all were removed at once to the open air and examined. Out of 60 or 70 insects two very young ones were alive. In a Florence flask with the mouth wrapped thickly with cotton mosquitoes (culex pungens) were killed in four minutes. Small black ants in test-tubes plugged with one inch of cotton were killed in five minutes. Rats in cages fell in convulsions in from two minutes to three and a half minutes from the beginning of the evolution of gas and ceased to move in from 30 to 40 seconds after falling. Mice and guinea-pigs succumbed more easily than did rats. Dr. Fulton and Dr. Stokes conclude that in hydrocyanic acid gas an exceedingly rapid and powerful agent is available for the destruction of all animal and insect pests within all fairly tight enclosures, and they point out that by its prompt action on mosquitoes, rats, and flies it is likely to be useful in the prophylaxis of yellow fever, malaria, filariasis, plague, and enteric fever. The gas is, of course, extremely dangerous to man, but they say that it is by no means unmanageable. After each of the experiments the room was entered instantly for the purpose of removing insects and animals, no other precaution being used than the suspension of respiration while in the room.

## AN OPERATION FOR THE REMOVAL OF PROMINENT ALVEOLAR PROCESS OF THE MAXILLA.

AN undue prominence of the anterior portion of the maxilla, even when edentulous, is often a source of much trouble to the dental surgeon who is anxious to insert a satisfactory and artistic denture. In the January issue of the *International Dental Journal* Dr. W. Howard records a case where the difficulty was overcome by removing a portion of the prominent bone. An incision was made from the region of the canine on one side to that on the other, the line taken being along the summit of the alveolar process. The muco-periosteum was raised and the bone was exposed for some distance both on the labial and the palatal aspects. The alveolus was then removed with bone-clippers to a depth of from one quarter to half an inch from the canine to the canine. The rough edges of the bone were smoothed and the muco-periosteum was then replaced and trimmed, a sufficient amount being allowed for shrinkage. The edges of the wound were united with catgut sutures. The result was in all respects satisfactory from an æsthetic point of view.

## IMMUNITY FROM SMALL-POX.

WE have received a letter from a correspondent pointing out that although the statistics recently published in relation to the present outbreak of small-pox afford useful information regarding the number of vaccinated and unvaccinated persons attacked by the disease, yet no mention is made of cases occurring in persons who have not only been previously vaccinated but have also had small-pox. One attack of the disease protects for a considerable period against a second attack, and should the patient again suffer from small-pox after an interval of some years the attack usually runs a mild course. Similarly, vaccination of a person who has had small-pox is rarely successful, but we are far from suggesting that such is always the case. We do not know of any recorded case of small-pox attacking a person who not only has previously had the disease but has also been subsequently successfully vaccinated. Many small-pox patients state that they have had a previous attack, but if careful inquiry is made into the symptoms, distribution of eruption, and duration of illness, and if the scars, if such be present, are examined, the alleged first attack usually proves to have been chicken-pox. Dr. J. MacCombie, writing in Professor T. Clifford Allbutt's "System of Medicine," states that in three-fourths of the cases of so-called second attack that have come under his notice he was able to satisfy himself that the first attack had been one of chicken-pox, and in most of the others there was not sufficient evidence to show whether the first attack had been small-pox or not.

## NURSING OF THE SICK POOR IN WORKHOUSES.

THE President of the Local Government Board has appointed from among the officers of the department a committee (consisting of Mr. Grant Lawson, M.P., Parliamentary secretary, Mr. W. E. Knollys, C.B., chief general inspector and one of the assistant secretaries, and Dr. A. H. Downes and Mr. A. Fuller, Poor-law medical inspectors, with Mr. R. H. A. G. Duff as secretary) to consider this subject. The committee will inquire and report as to the qualifications of nurses and probationers, the difficulties in obtaining an adequate supply of these officers, and the regulations necessary to define the respective duties of the master or matron and of the superintendent nurse.

## THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope, received at the Colonial Office on Jan. 15th, states that for the week ending Jan. 11th the cases of plague in the Cape Peninsula numbered 0. At Port Elizabeth there was one case, that of a coloured person. At Mossel Bay the cases numbered 2, both Europeans. In all the other places the cases numbered 0. The deaths from plague throughout the whole colony numbered 0. The area of infection remained unchanged; and the cases of plague in persons under naval and military control numbered 0. As regards Mauritius, a telegram from the Governor received at the Colonial Office on Jan. 17th states that for the week ending Jan. 16th the cases of plague numbered 27 of which 21 were fatal.

## THE INVESTIGATION OF CANCER.

SUNDRY paragraphs having appeared lately in the daily press concerning the investigation of the cause and treatment of cancer we think it well to state that we have authority to say that a draft scheme has been drawn up by an eminent surgeon which has been submitted to and received the approval of various leading members of the medical profession. It is proposed to raise a sum of money sufficient when invested for the income to defray the expenses of the investigation, and at a meeting held on Oct. 23rd, 1901, at which the Presidents of the Royal College of Physicians of London and of the Royal College of Surgeons of England, as well as nearly all the members of the special finance committee in connexion with the laboratories of those colleges respectively, were present, it was unanimously resolved :—

> That we cordially approve of a proposal which has been made to raise a sum of money, the interest of which shall be devoted to the investigation of the causes, prevention. and treatment of cancer. We are of the opinion that under the control of a suitably elected advisory committee an effective scheme could be drawn up, and that a convenient and suitable place for the investigations would be the laboratories belonging to the Royal Colleges.

We understand that considerable interest has been shown in and towards this movement by several highly placed and temperature record: 100° F. 3. The extensive formation of a friable granulation tissue exuding a thin serous discharge and the almost entire absence of suppuration. 4. The local character of the disease [illegible]

## SANITARY IMPROVEMENTS AT WINDSOR CASTLE.

CONSIDERABLE improvements, amounting to reconstruction, have been made in the sanitary arrangements of the southern part of Windsor Castle, recently occupied for a few days by their Majesties, by the officials of His Majesty's Office of Works under the advice and supervision of Professor W. H. Corfield, their consulting sanitary adviser. The whole of the drains under the south towers, from Edward the Third's Tower to the Victoria Tower inclusive, have been done away with, so that there is now no drain under the buildings on that side of the castle, and new watertight iron drains have been laid outside the buildings. Internal water-closets and soil-pipes have been cleared away, ventilated lobbies formed in connexion with the water-closets, new soil-pipes fixed outside the building, and the best improved appliances of all kinds fixed. Suitable disconnexion arrangements have been provided between the new drains of these towers and the castle sewers, so that each of the towers is, in fact, so far as the drainage is concerned, a house in itself. Similar improvements, we are informed, will gradually be carried out throughout the rest of the castle.

## THE DIFFERENTIAL DIAGNOSIS OF SIMPLE ABDOMINAL CONTUSION AND OF CONTUSION WITH INTESTINAL INJURY.

THE *Boston Medical and Surgical Journal* of Dec. 5th, 1901, contains a valuable paper on this subject by Dr. John T. Bottomley. He points out the difficulty of obtaining reliable statistics and pleads for a careful study of cases of abdominal contusion in the first few hours so as to assist in the solution of the all-important question of the time at which an operation should be performed. He has himself adopted the method of comparing all the available cases (20) of undoubted severe intestinal injury from contusion admitted to the Boston City Hospital (undoubted because proven by necropsy, operation, or death from acute peritonitis) with an equal number of cases of undoubted simple contusion (undoubted because the symptoms disappeared in a few days) The latter were *chosen* cases only in that an attempt was made to obtain cases of simple contusion as nearly as possible identical with those of intestinal injury. The following were the causes in both classes: striking by a wagon shaft, falls from various heights, kicks (human and equine), being run over, being fallen on or struck by objects, and squeezing. Thus causes apparently identical may produce a trivial or severe injury. But severe well-localised violence is usually an important factor in intestinal injury. Injuries caused by flying objects such as pieces of board from circular saws are liable to be serious. Injuries which are quite similar may cause profound shock in one patient and none in another; the pain may be intense in one and slight in another. Pain was present in all the cases of intestinal injury and in all but one of those of simple contusion. It may be the only symptom of a most severe injury—e.g., complete rupture of the ileum. Vomiting occurred on admission in 10 cases of each class; it was absent in two cases of intestinal injury and in seven of simple contusion, but in about half the cases (of either class) in which it was absent on admission it appeared within 2 hours. Its appearance late in, or after, the first 24 hours is usually of serious import. As to shock, muscular spasm, distension, tenderness, external signs of violence (contusion, abrasion, or traumatic hernia), dulness, alterations of temperature and pulse, analyses of the two series of cases show that none of these symptoms can be relied upon in diagnosis. Of the 20 cases of intestinal injury operation was performed in 11, and in only one with success; the nine cases treated expectantly were all fatal. In the successful case operation was performed in less than four hours after admission; four cases were operated on five or six hours after admission, one 12 hours, four 24 hours, and one 48 hours. In the cases not operated on the average duration of life after the injury was 2·33 days, the extremes being seven days and one day. In the cases of simple contusion the symptoms disappeared on an average in 4·43 days; in two cases exploratory incisions were made; nothing was found, and uneventful recovery ensued. Dr. Bottomley concludes that no sign or combination of signs indicates the nature of the injury and that the only means of making a diagnosis sufficiently early for treatment is by laparotomy. To wait for symptoms of peritonitis is, he says, to wait too long. Improvement in the first few hours may be deceptive; it may be only reaction from shock and should, he thinks, furnish the opportunity for operation. Many operations would be no doubt performed in cases in which there is no intestinal injury, but they are attended with little danger. Nimier[1] states that of 307 cases of abdominal contusion treated expectantly 92 were fatal, and Schmitt says that the expectant treatment of cases of abdominal contusion sufficiently severe to suggest perforation gave a mortality of 97·5 per cent.[2] On the other hand, Petry found that the mortality of 42 similar cases treated by laparotomy was 66·7 per cent. Kirstein had a mortality of 55·5 per cent. in 18 cases; in four laparotomy was done within five hours of injury and all were successful. His statistics show that every hour that passes after the injury lessens the chance of recovery after operation. Dr. Bottomley's careful analysis is disappointing in that he arrives at the purely negative conclusion that early diagnosis of the nature of the injury is impossible; but even if his view as to laparotomy be not accepted his ingenious and original method of attacking a very difficult problem is admirable and he has clearly established a most important fact—i.e., the close similarity of the early symptoms of simple abdominal contusion and of contusion with rupture of the intestine, which should be a warning to the practitioner to regard every case with anxiety.

## HYDROCYANIC ACID GAS IN PUBLIC HEALTH WORK.

UNDER this title Dr. John S. Fulton and Dr. William R. Stokes of Baltimore describe in the December number of the *Maryland Medical Journal* a variety of experiments on the destruction of bacterial, insect, and animal life by means of hydrocyanic acid gas. The chemicals employed were cyanide of potassium, concentrated sulphuric acid, and water, in the relative proportions of 1, 1·5, and 2·25. The amount of gas to be used was expressed in terms of cyanide—so many grammes of cyanide per 100 cubic feet of enclosed space. The following composed the apparatus in which the gas was generated. Three jars, placed at suitable relative elevations, were connected by syphon tubes. The requisite amount of cyanide was placed in the lowest and largest jar. The intermediate jar contained the water, and the upper jar the concentrated acid. The lower of the two syphons was automatic, and actuated by a definite height of liquid in the intermediate jar. It did not therefore operate until the last few ounces of acid were being delivered from the upper jar into the intermediate one. By this means the operator had time to leave the room and to close it behind him, and there was no danger of effervescence causing the chemicals to escape from their containers. The amount of

*Absorptive bases.*—In this class of ointments the basis must not only penetrate but pass through the skin. Purified and hydrated wool-fat possesses this property in a high degree because, it is supposed, of its power to absorb more than its weight of water, and also because it is not a true fat but a cholesterin analogous to the sebaceous secretion. It has other advantages, being practically unalterable, never becoming rancid, and, when pure, not being affected by medicinal agents. Experiments reported by Unna, Shoemaker, Kiernan, and others have demonstrated its great absorptive power, ointments of narcotic extracts with this basis being effective in twice the dose given by the mouth; quinine, potassium iodide, and mercury produced their constitutional effects and were found in the urine shortly after inunction with ointments containing these agents with wool-fat. It is said to be especially useful in application to the orifices of the body in genito-urinary practice, and for other purposes. It is often mixed with oil, wax, and especially theobroma oil, and Helbing uses the following mixture, the addition of paraffin and wax reducing its absorptive power equal to that of lard: hydrous wool-fat, 65 parts; paraffin, 30 parts; ceresin, 5 parts. Such mixtures are largely used as substitutes for lard or oils, owing to their freedom from rancidity and their resistance to chemical agents, while possessing the same rate of absorption as the animal and vegetable fats and oils. The experiments of Shoemaker go to prove that the oleates do not pass through the skin, but exercise an intra-cutaneous effect; they cannot, therefore, be used for producing systemic effects; undiluted wool-fat should be used when systemic effects are desired. The 1898 British Pharmacopœia directs hydrous wool-fat to be used in the preparation of hamamelis and hemlock ointments.

# A DECADE OF PUBLIC HEALTH WORK IN THE ADMINISTRATIVE COUNTY OF LONDON.

## II[1]

READERS of Mr. Shirley Murphy's previous reports will be prepared to find that a large portion of the volume before us is occupied with a discussion of the behaviour of preventable disease in London during the year 1900. The zymotic—or, as the Royal College of Physicians of London prefers to call them, the epidemic—group of diseases first comes under consideration. And here we are pleased to notice what is, if we mistake not, an entirely new departure in these reports. We refer to a series of diagrams showing the seasonal distribution in London of each of the common infectious diseases in the successive weeks of a long series of years. By means of a curve the mean mortality in each week is shown as a percentage above or below the mean for the year, and by the help of these diagrams it is possible to forecast with some approach to accuracy what will be the probable course of a given disease at any desired period of the year. For example, to take the case of small-pox, the diagram for this disease is based upon the mortality experience of 60 years (1841–1900). The curve exhibits two maxima, the first corresponding with the end of January and the beginning of February and the second corresponding with the fourth week of May. The curve reaches the mean line, which is represented by 14 weekly deaths, in the first week of July; it then further steadily falls until the end of September, when it touches the lowest point, and thereafter as steadily rises until it again reaches the mean line in the third week of December. According to the experience of the last 60 years, then, we see that in London small-pox attains its greatest prevalence during the first half and its least prevalence throughout the second half of the year. In this respect it contrasts strongly with scarlet fever, diphtheria, and enteric fever, all of which diseases, if their rate of mortality is to be trusted, show diminished prevalence during the earlier months and increased prevalence during the later months of the year.

These instructive diagrams are a development of a like series prepared 10 years ago by Dr. W. Ogle of the General Register Office. Mr. Shirley Murphy has, however, brought them up to date and consequently has greatly increased their value for statistical purposes. We recognise the appropriateness of their appearance in the reports of the county medical officer of health rather than in those of a Government department. It is much to be desired that, if possible, Mr. Shirley Murphy will insert in his future reports similar curves showing reported *attacks* (instead of deaths) for each of the common infectious diseases that are notifiable under the London Act of 1889. There is no question that a set of diagrams so constructed and based on the experience of the metropolis for a period of ten years would be simply invaluable for administrative sanitary purposes.

In view of the existing serious prevalence of small-pox amongst us Mr. Shirley Murphy's remarks concerning the earlier cases of this disease that appeared in London during 1900 will be of special interest at the present time. It appears that in the course of the year 86 persons in all were *certified* to be suffering from small-pox, but in 13 of these cases subsequent examination showed that there had been errors in diagnosis. London had been free from small-pox during the last six months of 1899, and although in the course of 1900 several cases were imported from abroad, the disease never became established within the county until after its close.

"It is well deserving of note," Mr. Shirley Murphy says, "that much of the small-pox in London in 1900 had its origin in infection received abroad. The first case of the group of 18 cases, occurring mostly in Hackney, was that of a boy living in proximity to the Eastern Hospital, the date of whose attack appears to coincide in point of time with those of patients in the Eastern Hospital who had been infected by a man in that hospital who was admitted on Dec. 7th, and was removed, suffering from small-pox, on Dec. 9th, 1899. This man had returned from Jerusalem suffering from small-pox. If this explanation of the boy's illness be correct some 25 cases of small-pox had their origin in this source." Other instances are given in the report which show that infection had been imported several times from Paris and other foreign parts in the course of the year, but that in every case the measures adopted by the local sanitary authorities were successful in limiting the spread of the disease. Speaking of the changing age incidence of small-pox mortality in London in successive periods since 1841, Mr. Shirley Murphy points out that whereas in the period 1842–1850 the deaths of children under five years of age constituted nearly 70 per cent. of the total deaths, the proportion steadily fell in subsequent decennia until it reached a minimum of 25 per cent. in the 10 years 1881–90. The reduction in successive periods was undoubtedly due to more complete vaccination of the infant population, and the increase in the mortality at early ages which has been observed since 1890 corresponds almost exactly with the growing neglect of infant vaccination which is shown in a table to have taken place in recent years. It is an ominous fact to which public attention cannot be too forcibly directed that in the year 1898 (the latest for which returns are available) about one-third of the infant population of London below the age of one year were unvaccinated.

The incidence of scarlet fever in 1900 was below the normal, and so likewise was the virulence of the attacks as measured by their case mortality. For this reason the medical officers of health of the various districts have had less occasion than in other recent years to comment on special outbreaks of that disease. We note, however, that in the year under present review, as in previous years, school attendance excited a marked influence on the spread of scarlet fever amongst children of school age. The summer holidays of the London board schools in 1900 began on July 26th—i.e., in the latter part of the thirtieth week of the year—and the schools re-opened on August 27th—i.e., at the beginning of the thirty-fifth week. From a table given in the report we find that during the holiday period—namely, the interval between the thirty-second and thirty-fifth week—the incidence of scarlet fever upon children of from three to 13 years of age was *below* the average by nearly 16 per cent., whereas in the four weeks following the holidays the incidence rose to 69 per cent. *above* the average. It is therefore impossible to avoid the conclusion that school attendance was largely responsible for this difference in the spread of scarlet fever, more especially since the statistics of previous years have pointed to a similar conclusion. Exactly the same lesson is derivable from the statistics of diphtheria. In the year 1900, as in wealthy personages and there is good reason for thinking that success will attend it if some effort is now made. In view of what has already been done in Germany, the United States, and in Italy it is quite time that this country should bestir itself in the matter. As soon as the scheme has been made public we shall return to the consideration of the question.

## THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

DR. F. W. PAVY, F.R.S., has been elected to the office of President of the National Committee for Great Britain and Ireland of the International Congress of Medicine, in place of the late Sir William Mac Cormac, Bart., K.C.B., who so worthily filled the office for many years.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE courses of lectures to be delivered at the Royal College of Surgeons of England during 1902 are as follows: On Monday, Wednesday, and Friday, Feb. 10th, 12th, and 14th, Mr. C. P. White, Erasmus Wilson Lecturer, will give lectures on the General Pathology of Tumours; on Feb. 17th, 19th, and 21st Dr. T. G. Brodie, Arris and Gale Lecturer, will lecture on the Pulmonary Circulation, more particularly in relationship to Variations in Cardiac Activity; on Feb. 24th, 26th, and 28th Professor W. McAdam Eccles will lecture on the Anatomy, Physiology, and Pathology of the Imperfectly Descended Testis. The first lecture will deal with the anatomy, the second with the physiology and a portion of the pathology, and the third with the rest of the pathology. Each lecture will be illustrated by lantern slides. On March 3rd, 5th, and 7th Professor F. G. Parsons will lecture on the Blood-vessels of Mammals in relation to those of Man; and on March 10th, 12th, 14th, 17th, 19th, and 21st Professor C. Stewart, F.R.S., will lecture on Organs of Respiration. All the lectures will commence at 5 P.M.

THE first place on Wednesday, Feb. 26th, has been obtained by ballot for the second reading of a Bill "to secure the better training of midwives and to regulate their practice."

THE annual dinner of the West London Medico-Chirurgical Society will take place on Wednesday, Feb. 19th, at 7.30 P.M., at Frascati's, Oxford-street, W.

THE KING has approved of the appointment of Dr. Wroughton Gerald Heath, medical officer of Montserrat, to the Legislative Council of that Presidency.

# Pharmacological Notes.

### OINTMENTS AND OINTMENT BASES.

IT is satisfactory to find that the ointments of the 1898 edition of the British Pharmacopœia have earned the commendation of those who are responsible for the preparation of the forthcoming United States Pharmacopœia. According to C. S. N. Hallberg, Ph G.,[1] these ointments, in the opinion of the United States Pharmacopœia Committee of Revision, are a vast advance over those of any and all other pharmacopœias, excepting the German and Austrian (1900) revised editions, which have not yet been studied. In a preliminary report by the sub-committee on ointments it is shown that in previous United States pharmacopœias the various bases for ointments have been chosen solely for pharmaceutical reasons and without any discrimination as to the general therapeutical purposes of this form of medication. Considered from the therapeutical standard the ointments may be divided into three groups, as follows:—

1. Protective: Non-absorbent or epidermatic.
2. Emollient: Nutritive, absorbent, or endermatic.
3. Constitutional, systemic: Absorptive or diadermatic.

These generalisations, though empirical, afford a basis for the study of these preparations in the light of the present state of medical science. The researches of Unna, Liebreich, and Shoemaker have demonstrated the necessity of taking the character of the fat into consideration, in order that the desired effect of an ointment may be obtained. Shoemaker, in "Ointments and Oleates," says: "That the oleaginous basis possesses valuable physiological and therapeutical properties peculiar to itself is proven by the fact that the sebaceous secretion of the skin is of an oleaginous composition and consistence. In estimating the value of an ointment we must take into consideration the separate virtues of the fatty basis and the included drug or drugs. ...... Sebum consists of fat cells, free fat and epithelial débris, and has the following chemical composition: olein and palmitin, 40 per cent.; casein, 13 per cent.; gelatin, 8 per cent.; water, 35 per cent.; and small quantities of sodium chloride, phosphate, and sulphate. It is unmistakeably a natural or physiologic unguent." The sebum is related to the nutrition of the hair, maintains the skin in a soft and flexible condition, fortifies it against changes in temperature by regulating the heat, acts as a lubricant, thus obviating deleterious friction, and is protective against irritant discharges. It acts as a preservative to the cuticle, protecting it from maceration by excessive perspiration and consequent exposure of the sensitive cutis vera. The varied uses of ointments are indicated by this enumeration of the properties and functions of the sebum; and the foregoing classification is useful in discussing the choice of ointment bases.

*Non-absorbent bases.*—When a purely external contact is desired the paraffins in their three different forms—viz., liquid, soft, and hard paraffins—afford the best bases. Such ointments may be required as (1) protectives; (2) antiseptics; (3) *astringents*; (4) *counter-irritants*; (5) germicides; and (6) parasiticides. These paraffins should be bland and neutral; sometimes they produce irritating and stimulating effects instead of being purely protective, lubricating, or emollient; these ill-effects are ascribed to sulphur and other impurities. These bases are used for the following drugs in the 1898 British Pharmacopœia: the nitrate, red and yellow oxides, and red iodide of mercury, ammoniated mercury, zinc oleate, creosote, eucalyptus oil, boric, salicylic, and carbolic acids, glycerin of lead subacetate, iodoform, and the carbonate and iodide of lead.

*Emollient—absorbent bases.*—Lard, sometimes with an addition of wax and oil, and, in the case of alkaloids, of oleic acid, afford vehicles with a range of melting points well adapted to the varying pharmaceutical and therapeutical requirements of this class of ointments. Probably fresh, pure lard is the ideal basis for endermatic medication, but the commercial article, often an emulsion-like mixture of lard, tallow, cotton-seed oil, borax, and water, is unfit for use. Carefully prepared lard, benzoinated and preserved in a cool place, resists decomposition for a long time and answers admirably for the extemporaneous preparation of many ointments, but it is easily affected by many chemical reagents—e.g., the oxides of mercury. Lard in becoming rancid decomposes into fatty acids which produce irritation where an emollient effect is desired. Lard and bland animal and vegetable oils penetrate into, but not through, the integuments. Theobroma (cacao) oil affords one of the most elegant vehicles of this class, having an agreeable odour and not being prone to rancidity. As a nutrient cod-liver oil is the most effective when applied by inunction. These fats are intended for the following therapeutical purposes: emollient (also protective), anodyne, alterative, local irritant, resolvent, sedative, and stimulant. The drugs of this class officially used in the British Pharmacopœia include galls, opium, mercury, oleate, red iodide, subchloride and nitrate of mercury, sulphur, potassium iodide, chrysarobin, zinc oxide, belladonna, cantharidin, iodine, sulphur iodide, *the alkaloids aconitine, atropine, cocaine*, and veratrine, resin, stavesacre, capsicum, and liquid tar. The rosewater, compound mercury, and spermaceti ointments are also of this class.

---

[1] Pharmaceutical Journal, vol. lxvi., pp. 30 and 39.

granted by the county council for connecting the remainder of the drains of the asylum with the public sewer, and that a piece of ground which has a long frontage opposite the asylum grounds should be purchased for £500.

*Royal Asylum of Montrose (Annual Report for 1900).*—The average number of patients resident during the year was 661 and comprised 300 males and 361 females. During the year 190 patients were admitted, and of these 79 were males and 111 were females. The number of first admissions was 154—viz., 65 males and 89 females. Dr John G. Havelock, the medical superintendent, states in his report that in 50 of the cases admitted there was an acknowledged hereditary predisposition to insanity, in 31 there was a history of alcoholic intemperance, in 15 cases domestic troubles and business worries were assigned as the cause, in 15 old age appeared to be the determining factor, while in 42 no cause could be ascertained. The number of patients discharged as recovered during the year was 67, or 10·1 per cent. of the average number resident. The deaths during the year amounted to 57, or 8 6 per cent. as calculated on the same basis. Post-mortem examination was made in all cases where the consent of the relatives could be obtained. Of the deaths five were due to pneumonia, six to epilepsy, seven to general paralysis, seven to senile decay, 10 to cardiac disease, 11 to phthisis and other forms of tuberculosis, and the rest to other causes. Suicidal tendencies were marked in a large proportion of the patients admitted, and the inquiries of Sir John Sibbald now published for the first time show that Forfarshire and the neighbouring county of Kincardine have a larger proportion of suicides compared with the population than the rest of Scotland. The same authority states that "the counties of the east coast of Scotland all show higher suicidal rates than the western counties. It is curious that the city of Dundee shows a lower rate than the rest of Forfarshire. It is so far in favour of the view of those who say that Celticism and Catholicism prevent suicide, for Dundee contains the largest proportion of Irish Catholics of any part of Forfarshire." Certain parishes in the two counties named send a very high proportion of suicidal patients to the asylum and suicides are specially frequent in these parishes. "A possible explanation of this," says Dr. Havelock, "seems to be that of inherited predisposition, for the suicidal tendency is strongly hereditary in most cases and is prone to increase unduly in districts where the population is stagnant and stationary. The whole subject is beset with problems of extreme interest and difficulty." New villas are now completed and accommodate 60 male patients of the quiet and convalescent class. The cost with furnishings has amounted to less than £115 per bed. There is a notable increase of private patients paying the higher rates of board who are accommodated in Carnegie House. Additions and alterations in the form of electric lighting have been made throughout the building. The recent decision of the managers to join the Scottish asylums laboratory scheme is regarded as an important step in the right direction. The report of the house committee shows a profit in the farm and garden department of £416, but it records with regret a considerable deficit in the financial statement for the year. "This has been in great measure due to the same causes as last year, while the recent increase in patients' board has not yet come into full operation. Provisions have again risen in price and coal has increased in cost." The Commissioner in Lunacy states in his report that Carnegie House was found in admirable order, the surroundings of the patients being replete with every comfort. The patients in the asylum proper bore every evidence of being well cared for and their dress and personal appearance were satisfactory. The wards were clean and in good order and the medical registers were found to be kept with care and accuracy.

*Hereford County and City Asylum (Annual Report for 1900).*—The average number of patients resident during the year was 377 and comprised 177 males and 200 females. The admissions during the year amounted to 87—viz., 46 males and 41 females. Of these 64 were first admissions. Mr. C. S. Morrison, the medical superintendent, states in his report that "the influx of incurable senile cases is the most prominent and depressing feature of this asylum." The work of the staff is crippled by so excessive a proportion of helpless chronic and senile patients who present no prospect of recovery. The evil is to be remedied by having separate blocks for acute and curable cases, while the majority of the chronic helpless and incurable patients should be housed more cheaply in buildings erected at less cost. Nine males out of the 46 among the admissions were insane from the results of alcoholism. With respect to this Mr. Morrison observes that "these cases touch the fringe of a very large ethical State question of the necessity of promoting temperance by better education. We are to suppose that the flood of prosperity which has secured a higher wage to the labourer has been in excess of what his education and social environment have allowed him to expend in a more profitable way. ...... The increase of alcoholic insanity with a higher wage is not incidental to this country alone, but observable generally. ...... The natural enemy of all excesses should be the schoolmaster." The number of patients discharged as recovered during the year amounted to 31—viz., 15 males and 16 females, or 8 2 per cent. of the average number resident. The deaths during the year amounted to 32, comprising males and females in equal proportion, or 8·49 per cent. as calculated on the same basis. Of the deaths one was due to meningitis and cerebral hemorrhage, one to tuberculosis of the intestines, two each were due to epilepsy and general paralysis, two to asphyxia by choking, three to Bright's disease, 10 to senile decay, and the rest to other causes. Post-mortem examinations were made in 25 cases. Three inquests were held during the year, two on epileptics who had died from accidental suffocation, and one on a case of death following self-inflicted injuries previously to admission. For the first time in many years the asylum has been free from any influenza in a virulent epidemic form. This exemption is attributed chiefly to the "mildness of the winter, which never necessitated the over-heating of the air in the basement to maintain the necessary temperature. By over-heating we seem to lose some of the available moisture in the atmosphere necessary to maintain the healthy tone of the respiratory passages. ...... How far the evil necessity of such over-heating has conduced within recent years to increase in this asylum pulmonary phthisis is a matter needing further investigation." A number of patients had been boarded out for nearly 10 years, the cost of which has already reached £14,000, and it is now proposed that these patients should be brought back, as the boarding-out contracts are about to lapse. The asylum is to be enlarged to the extent of providing accommodation for 150 additional patients, and this, it is estimated, will cost about £30,300, representing in round figures £200 per bed. Electric illumination is installed throughout the new buildings and in the old blocks it will replace gas. The effluent from the sewage farm has been rendered innocuous and less offensive by the adoption of combined bacteria- and filter-beds and for the present they seem to be efficient. The Commissioners in Lunacy state in their report that the wards were bright, that the dormitories and bedding were in excellent condition, and that the appearance of the patients was neat and satisfactory. The medical case-books were very well kept

# Public Health and Poor Law.

## LOCAL GOVERNMENT BOARD.

### REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*On Recent Prevalence of Diphtheria in the Prestwich Urban District*, by Dr. THEODORE THOMSON.[1]—Prestwich, an outlying suburb of Manchester, with a population (including the Prestwich Asylum) of about 12,000, suffered in 1900 from a severe and sustained epidemic of diphtheria Dr. Thomson visited the district in consequence of the request of the Prestwich Urban District Council for local inquiry into the causes of this epidemic, and he revisited the locality in 1901 in view of the continued prevalence of the disease and with reference to sundry questions of sanitary administration. The epidemic of diphtheria in 1900 fell with great severity upon one portion of Prestwich, the village of Rooden Lane. In this village, with a population of some 3200, as many as 70 cases of diphtheria were notified, while the rest of the district contributed only six cases; and in 1901 Rooden Lane had 52 notified diphtheria cases, as against 12 which previous years, the spread of this disease also seems almost to have been determined, at any rate at school ages, by aggregation of the children at school.

---

[1] London: Eyre and Spottiswoode, East Harding-street; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby. Price 2d.

From the table respecting diphtheria we find that whilst in the holiday period the attacks amongst children of the ages of from three to 13 years were *below* the average by 32 per cent., they were 45 per cent. *above* the average in the four weeks succeeding the holiday period. Diphtheria seems to have shown less prevalence in London as a whole during 1900 than the average of the previous four years. The disease showed the greatest proportional prevalence in the districts of St. Saviour Southwark, Fulham, Stoke Newington, Plumstead, Lee, and Camberwell; and the least in St. Martin-in-the Fields, Paddington, and St. George's Hanover-square. The mortality from diphtheria in London as a whole in 1900 was considerably below the average; it was equal to 0·34 per 1000 of the population, against an average rate of 0·49 per 1000 in the 10-year period 1890–99. Enteric fever was notified during the year under review in 4317 cases, giving a ratio of 1 0 attack in each 1000 of the London population, as compared with an average ratio of 0 8 per 1000 in the previous 10 years. The death-rate from this disease in the county generally was equal to 0·16 per 1000, a rate which, although slightly lower than that of the immediately preceding year, was nevertheless, with that exception, higher than the rate in any year since 1893. In the distribution of enteric fever mortality in 1900 the northern and eastern groups were above, and the western and central groups were below, the average rate for London. In discussing the causes of enteric fever in London the reports of several of the local health officers give accounts of the communication of infection from one person to another. Dr. Reginald Dudfield observed this in four instances; Dr. L. C. Parkes speaks of the extension of the disease from one member of a family to seven others; Dr. J. F. J. Sykes gives account of two households in St Pancras in one of which the first case was followed by six others and in the second by nine others; Dr. G. Newman connects nine cases in Clerkenwell with one or other of three cases occurring among children attending the same school; Dr. L. T. F. Bryett gives particulars of six series of such cases occurring in Shoreditch; Mr. C. R. Kempster attributes a group of cases occurring in Battersea to the same cause; and Dr. W. A. Bond mentions the case of two nurses who were infected while in attendance upon cases of this disease. The above instances are confirmatory of the evidence which has been accumulating for many years past in the experience of hospital physicians and others and which affirms the communicable nature of enteric fever *under certain conditions.* We know of a physician of long experience in the hospital isolation of cases of enteric fever who distinctly asserts the infective character of this disease; he further states that his own painful experience of this fact in the persons of several members of his staff has caused him to avoid the employment of young and presumably susceptible nurses in the treatment of enteric fever and to restrict the nursing of that disease either to those who have been rendered immune by a previous attack or to the older members of the staff.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Jan. 16th, Mr. H. G. HOWSE, the President, being in the chair.

The SECRETARY reported that he had not received any essay on the Diagnosis and Treatment of Bullet Wounds of the Chest and Abdomen, the subject of the Jacksonian Prize for the past year. It was resolved that the amount of the dividends accruing from the Jacksonian Fund for the past year should be added to the principal of the fund.

The PRESIDENT stated that he would deliver the Hunterian Oration in 1903.

A letter was read from Mr. Herbert W. Page expressing the wish to resign his seat on the Court of Examiners at the end of the pass examination for the Membership to be held this month. The PRESIDENT stated that the vacancy thus occasioned would be filled up at the ordinary meeting of the Council in March, and that the vacancies which would be occasioned by the expiration of the periods of office of Mr. W. J. Walsham and Sir William H. Bennett would also be filled up at that meeting, Mr. Walsham not being a candidate for re-election.

Mr. T. Bryant was re-elected as representative of the College on the Council of the Queen Victoria Jubilee Institute for Nurses for three years.

A letter was read from Lady MacCormac thanking the Council for the sympathy expressed to her on the death of her husband.

A letter was read from the Secretary of the Medical Board of St. Luke's General Hospital, Ottawa, communicating a resolution adopted by the members of the medical staff of the hospital expressing regret at the death of Sir William MacCormac, and recording their appreciation of his efforts in the cause of science and the advancement of the best interests of the medical profession.

A letter was read from the President and General Secretary of the Fourteenth International Medical Congress to be held in Madrid from April 23rd to 30th, 1903, inviting the College to send a delegate to the Congress. Mr. Edmund Owen was appointed the delegate

A letter was read from Mr. Bryant reporting the proceedings of the General Medical Council at their late session. The thanks of the Council were given to Mr. Bryant for his services as the representative of the College on the General Medical Council.

On the motion of Mr. EDMUND OWEN it was resolved that the names of the Honorary Fellows should be continuously printed in the College Calendar and that in case of death the date thereof should be appended.

The March meeting of the Council will be held on Thursday, March 20th.

## ASYLUM REPORTS.

*Devon County Asylum (Annual Report for 1900).*—The average number of patients resident during the year was 1166, comprising 486 males and 680 females. The number of cases admitted during the year was 249, and of these 222—viz., 100 males and 122 females—were first admissions. The admissions exceeded those of the previous year by 32. Mr. Arthur N. Davis, the medical superintendent, states in his report that the *number of admissions* during the year was, with one exception, the largest in any one year since the opening of the asylum. The number of cases discharged as recovered during the year amounted to 112—viz., 44 males and 68 females, or 9 6 per cent. of the average number resident. The deaths during the year amounted to 85—viz., 47 males and 38 females, or 7 29 per cent. as calculated on the same basis. The mean average age at death for both sexes was 58 years. No inquest was held during the year. The casualties during the year amounted to eight and were principally the result of falls among aged patients, but in no case was death consequent upon the injury. Of the deaths two were due to nephritis, three to colitis, four to cerebral hemorrhage, four to cardiac disease, seven to epilepsy, nine to senile decay, 10 to phthisis and general tuberculosis, 11 to pneumonia, 20 to general paralysis of the insane, and the rest to other causes. *There has been no illness* of an epidemic character, but there were two cases of enteric fever and several cases of erysipelas and influenza. "On the whole the general health of the patients has been good, notwithstanding the continued accumulation of old and feeble cases." Among the principal causes of insanity in the admissions hereditary influences were found in 26 cases, previous attacks in 25, alcoholic intemperance in 15, and senile mental decay in 17. *Employment in the garden and on the* farm for the male patients has been freely provided and with great benefit. "In the workshops only a limited number find employment on the male side, but a very large proportion of the women are usefully engaged in the needle-room, laundry, and wards." The Commissioners in Lunacy state in their report that the general appearance of the day-rooms, wards, and dormitories has been much improved and speaks well for the management. *Some degree of overcrowding* still exists on the male side. The condition of the patients in respect to personal tidiness was satisfactory, and the medical records and post-mortem notes were well and carefully kept. The committee of visitors to the asylum state in their report that the weekly charge of maintenance per patient has been raised from *8s 9d.* to *9s. 3d.* The committee have recommended that the sum of £500 should be

The annual rate of mortality in these towns, which had been 20·1 and 18·3 per 1000 in the two preceding weeks, further declined last week to 17·7 per 1000. In London the death-rate was 18·0 per 1000, while it averaged 17·6 in the 74 other large towns. The lowest death-rates in these towns were 4·8 in Hornsey, 8·0 in Derby, 9·2 in Smethwick, 10·3 in Kings Norton, 10·7 in Birkenhead, and 10·8 in Walthamstow; the highest rates were 24·0 in Wolverhampton and in West Hartlepool, 24·1 in Bolton, 24·2 in Stockton-on-Tees, 27·9 in St. Helen's, and 31·8 in Merthyr Tydfil. The 5035 deaths in these towns included 534 which were referred to the principal zymotic diseases, against 510 and 482 in the two preceding weeks; of these 534 deaths 158 resulted from measles, 90 from whooping-cough, 85 from diphtheria, 59 from small-pox, 57 from scarlet fever, 50 from diarrhœa, and 35 from "fever" (principally enteric). No death from any of these diseases was registered in Hastings, Southampton, Ipswich, Burton-on-Trent, West Bromwich, Derby, Wallasey, Wigan, Warrington, Rochdale, or West Hartlepool; the highest zymotic death-rates were recorded in Great Yarmouth, Handsworth, Aston Manor, Oldham, Rotherham, Stockton-on-Tees, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Great Yarmouth, Aston Manor, Stockport, Oldham, Preston, Rotherham, Stockton-on-Tees, South Shields, and Merthyr Tydfil; from scarlet fever in Aston Manor, Handsworth, St. Helens, and Bolton; from diphtheria in Hanley; and from whooping-cough in Stockton-on-Tees. The mortality from "fever" showed no marked excess in any of the large towns. 55 deaths from small-pox were registered in London, three in Tottenham, and one in Hornsey, but not one in any other of the 75 large towns. The number of small-pox patients in the Metropolitan Asylums hospitals, which had been 666, 754, and 873 at the end of the three preceding weeks, had further risen to 877 on Saturday, Jan. 18th; 213 new cases were admitted during the week, against 226, 261, and 306 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2760, against 3137, 2987, and 2864 on the three preceding Saturdays; 288 new cases were admitted during the week, against 263, 313, and 250 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 452 and 366 in the two preceding weeks, further declined last week to 307, and were 296 below the corrected average. The causes of 65, or 1·3 per cent., of the deaths in the 75 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Salford, Bradford, Leeds, and 37 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Aston Manor, Liverpool, St. Helens, and Middlesbrough.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·2 and 19·6 per 1000 in the two preceding weeks, rose again last week to 20·8 per 1000 and was 3·1 per 1000 above the mean rate during the same period in the 75 large English towns. The rates in the eight Scotch towns ranged from 14·1 in Leith and 17·1 in Edinburgh to 23·1 in Paisley and 23·5 in Glasgow. The 673 deaths in these towns included 23 which resulted from measles, 13 from diarrhœa, 11 from whooping-cough, six from scarlet fever, six from diphtheria, and four from "fever." In all 63 deaths were referred to these principal zymotic diseases last week, against 86, 70, and 56 in the three preceding weeks. These 63 deaths were equal to an annual rate of 2·0 per 1000, which was slightly above the mean rate last week from the same diseases in the 75 large English towns. The fatal cases of measles, which had been 36, 30, and 23 in the three preceding weeks, were again 23 last week, and included 20 in Glasgow and two in Dundee. The deaths from diarrhœa, which had been 12 and 19 in the two preceding weeks, declined again last week to 13, of which six occurred in Glasgow, four in Dundee, and three in Edinburgh. The fatal cases of whooping-cough, which had been 12 and five in the two preceding weeks, rose again to 11 last week, and included nine in Glasgow. The deaths from scarlet fever, which had been seven, four, and two in the three preceding weeks, increased again last week to six, of which three were registered in Greenock. The fatal cases of diphtheria, which had been eight, five, and four in the three preceding weeks, rose again to six last week, and included two in Edinburgh and two in Dundee. The deaths from "fever," which had been seven and three in the two preceding weeks, increased last week to four, of which two occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 182 and 142 in the two preceding weeks, rose again last week to 176, and showed an excess of 37 over the number in the corresponding period of last year. The causes of 18, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·4 and 25·0 per 1000 in the two preceding weeks, further declined to 23·4 per 1000 during the week ending Jan. 18th. During the past four weeks the death-rate has averaged 26·2 per 1000, the rates during the same period being 19·5 in London and 20·5 in Edinburgh. The 170 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 12 from the number in the preceding week, and included six which were referred to the principal zymotic diseases, against nine and 10 in the two preceding weeks; of these two resulted from diarrhœa, one from measles, one from diphtheria, and one from "fever." These six deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rates during the same period being 2·2 in London and 1·0 in Edinburgh. The mortality from diarrhœa slightly exceeded that recorded in the preceding week; while that from diphtheria and from "fever" showed a decline. The 170 deaths in Dublin last week included 39 of children under one year of age and 52 of persons aged 60 years and upwards; the deaths of infants showed a marked increase over the number in the preceding week, while those of elderly persons slightly declined. One death from violence and two inquest cases were registered; and 58, or more than a third, of the deaths occurred in public institutions. The causes of 10, or nearly 6 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon Robert William Williams has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets. Dated Jan. 10th, 1902.

### ARMY MEDICAL STAFF.

Surgeon-General Thomas Francis O'Dwyer is placed on retired pay. Dated Dec. 26th, 1901.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel A. O. Geoghegan is appointed to the charge of the Station Hospital at Shahjehanpur. Colonel J. F. Supple, Principal Medical Officer, Bombay and Nagpur Districts, proceeds to Poona to officiate as Principal Medical Officer, Bombay command. Lieutenant-Colonel W. O. Wolseley, in medical charge of the Station Hospital, Belgaum, has proceeded to Bombay to officiate as Principal Medical Officer, Bombay and Nagpur Districts.

### IMPERIAL YEOMANRY.

Essex: J. J. Macgregor to be Surgeon-Lieutenant.

### INDIA AND THE INDIAN MEDICAL SERVICES.

The King has approved of the retirement from the service of the undermentioned officers:—*Bengal Establishment:* Lieutenant-Colonel Edward Bovill, dated Nov. 8th, 1901. Captain Albert Edwin Hayward Pinch, half-pay list, dated Dec. 17th, 1901. *Madras Establishment:* Lieutenant-Colonel Mervanji Pestanji Kharegat, dated August 8th, 1901.

### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain E. W. Barnes to be Surgeon-Major. Surgeon-Captain William Baron Cockill, 2nd Volunteer Battalion the Border Regiment, to be Surgeon-Captain.

### VOLUNTEER CORPS.

*Rifle:* 2nd Cadet Battalion the King's Liverpool Regiment: Henry James Bailey to be Surgeon-Lieutenant. 2nd occurred in the rest of the district Dr Thomson was able to dismiss the possibility of milk having served in this instance as an agent in the dissemination of diphtheria With regard to the question whether various unwholesome conditions which were met with in Rooden Lane (e g , privy midden nuisances, unpaved yards, and house drains connected directly to sewers) played a part in promoting the recent prevalence of diphtheria his report speaks with suitable caution "in our present uncertainty as to the conditions particularly favourable to the life and growth of the diphtheria bacillus" It would be greatly to the advantage of the public health if careful research could be undertaken which would make it possible to express a more certain opinion on this matter and so to determine how far diphtheria is capable of repression by preventive measures specially directed against insanitary surroundings of dwellings There appears to be no doubt that at Rooden Lane the spread of diphtheria was aided, and perhaps largely aided, by the transmission of infection from the unrecognised sick *to the healthy while at school together* Closure of schools had a distinctly beneficial influence Moreover, the fact that scarcely any diphtheria occurred in the village of Prestwich, only half a mile from Rooden, has to be associated with the circumstance that each of these villages has its own public elementary schools and that there is but little attendance of children from the one village at the schools of the other While pointing out defects in administrative action in certain directions Dr Thomson shows that, on the whole, the measures to combat diphtheria adopted by the district council and its officers were *thorough* Antitoxin inoculation was used on a considerable scale as a preventive measure, but the degree of success obtained is not indicated in the report. Mr T Stephenson, the medical officer of health, made a practice of examining the throats of the children attending school, with satisfactory result Dr Thomson's observations as regards the general sanitary circumstances of Prestwich district are less favourable to its local sanitary administration, and he points to a number of conditions which it is to be hoped that the district council will take steps to remedy Though the privy-midden has been often condemned we cannot refrain from quoting Dr Thomson on the subject —

> No worse conservancy system for populous localities has yet been invented than the privy midden capacious deep usually permitting soakage of its liquid contents into the surrounding soil and above all foul smelling Its occasional cleansings lead to further fouling of the ground on which by way of preliminary to removal its contents are thrown Only noses inured to stinks can tolerate such a system and no such noses should be found among those whose duty it is to act as guardians of the public health

*On the Sanitary Circumstances and Administration of the Gildersome Urban District, and upon Recent Prevalence of Enteric Fever therein* by Dr W W E FLETCHER [2]—This report records some interesting facts with regard to a small outbreak of enteric fever attributable to contamination of a particular milk supply Gildersome for several months antecedent to March, 1901 had been suffering somewhat excessively from "sporadic enteric fever, occurring in different parts of the district and not attributable so far as could be ascertained to any single common cause of infection But from March 7th to April 15th 25 cases of enteric fever were notified from 18 houses Of these households 16 were supplied by a particular milk seller Dr Fletcher ascertained that two members of the family of this milk seller had been attacked during February by illness which it seems certain in the light of subsequent events was enteric fever, and on March 9th another member of this family had an undoubted attack of the disease The milk seller in question was a man in a small way of business, and the householders who suffered from fever formed a large proportion of his customers The way in which the milk may have become infected at the milk seller's does not appear to be indicated in the report, no doubt because no trustworthy facts could be ascertained The facts given by Dr Fletcher with regard to the sanitary condition and administration of Gildersome indicate that this small district belongs to a type which may be expected to become common in certain counties—a locality which has only in recent times become urban in character, but which is already losing its population by reason of the exhaustion of its local coal mines. Such districts present particular difficulties as regards sanitary improvements Amendment is needed in many directions, but the district with a population of the working class which is now no more than 3000, has already borrowed some £12 000 and is obliged to spend a further large sum to complete its sewerage scheme Unless some new industries succeed in Gildersome it is probable that as years go on the population which remains will be less able to afford the rates required to repay the debt of the district, and correspondingly unwilling to incur any expense in matters of public health

*On the Sanitary Circumstances of the Llandilofawr Rural District Carmarthenshire, and on Sanitary Administration by the Rural District Council*, by Dr S W WHEATON [3]—This report also deals with a colliery district Population has been steadily falling off in almost all the parishes of the large district of Llandilofawr in Carmarthenshire, with the exception of the subdistrict of Llandebie, in the Amman Valley, where mining and manufactures are in progress In the greater part of the district are villages comprising many empty and dilapidated dwellings, while in Llandebie and its neighbourhood large collections of *dwellings of an urban character are springing* up These new houses leave much to be desired, for example their roofs are frequently without eave spouting and they have been constructed without damp proof courses It is evident that much stricter supervision of building operations is required The great trouble throughout the district, strange as it may seem when its hilly character and high rainfall are considered, is lack of water In Llandebie the inhabitants have to depend on three private wells, two of which are liable to serious contamination, in Penygroes the villagers have to go 400 yards away to a mere dipping place, which is apt to fail them in the summer, when they resort, as is common in this part of the country, to water coming from abandoned coal workings Dr Wheaton gives many striking instances of villages with unsatisfactory supplies and habitual scarcity of water The difficulties of obtaining a good public supply no doubt may be great in some of the villages in question, but it is evident that a great improvement could be effected in the majority of places (Llandebie for example) with very little difficulty Where there is abundance of water in watercourses and streams no care seems to be taken to prevent pollution Privies are frequently built over streams and refuse of all kinds is thrown into them The district council appears to have paid little attention to the advice of their medical officer of health in these or in other matters and they have insisted upon the reappointment of an inspector of nuisances who appears to be past his work The prospects of "sanitary progress' in Llandilofawr hardly seem bright, but it may be hoped that some improvement will follow the publication of Dr Wheaton's report

## VITAL STATISTICS

### *THE DEATH RATE OF 1901*

As all medical officers of health are now required to complete their annual reports to the Local Government Board by the middle of February in each year the following figures have been provisionally compiled for their convenience from the quarterly reports of the Registrar General

*England and Wales 1901 Annual Birth- and Death rates, and Rates from the Seven Chief Epidemic Diseases*

| — | Annual rates per 1000 living | | | Infant mortality |
|---|---|---|---|---|
| | Births | Deaths (all causes) | Deaths from seven chief epidemic diseases | Annual death rate of infants under one year per 1000 births |
| England and Wales | 28·5 | 16·0 | 2·05 | 151 |
| Rural England and Wales | 27·2 | 15·7 | 1·56 | 138 |
| 33 Great towns | 30·0 | 18·6 | 2·63 | 165 |
| 67 Smaller towns | 29·0 | 17·1 | 2·24 | 163 |

### HEALTH OF ENGLISH TOWNS

In 75 of the largest English towns 8629 births and 5035 deaths were registered during the week ending Jan 18th artery with his thumbs, and a third to prepare and to apply a tourniquet? May I put this question, How often can a lecturer get his class subject to bear the application of a tourniquet really tight enough to stop absolutely the arterial flow? Short of this, what does the demonstration amount to but of a partially tight tourniquet which in practice will indefinitely increase the hæmorrhage? It may be that this is the demonstration only too exactly imitated by some of the pupils.

---

[2] 1901 price 6d

[3] 1901, price 3d

Mr. J. B. G. Gidley-Moore asks me, in THE LANCET of Jan. 18th, p. 194, how I would deal with the case he quotes from the *Daily Mail* of a man who died before he could be taken to the hospital after having had *both legs* cut off by a chaff-cutter. I only know of the accident to *one arm* as seen in the country, the hand crushed by the rollers, or crushed and the fingers cut off. A hand was cut off and the bleeding arrested by plunging the forearm into a bag of flour. In a more extensive case a man's arm was drawn in to the elbow whilst the knives cut off his forearm in slices. Bleeding was checked by local pressure and he was taken two miles to a hospital where he got well. It must be some kind of very large chaff-cutter to draw in *both* a man's legs—they would first be crushed by the rollers before being cut off. The result would not be different from a railway accident. Owing to the shock and the crushed ends of the arteries there would be no great arterial hæmorrhage, so that the instruction to an elementary class as regards such an accident should be that elevation and local pressure is to be applied at once and the tourniquet reserved until the patient is anæsthetised and the surgeon is ready to explore the injury. Anything less than the rapid and efficient application of a tourniquet would only increase the bleeding and hurry on the end noted in the above case.

It is evident that elementary first-aid instruction would gain indefinitely and theoretical considerations drawn from surgical practice could be revised by the publication of reports of cases in which the nature of the accident, the time elapsing before the application of first aid, the exact nature of the first aid, the amount of instruction undergone by the person rendering it, and the condition of the patient when first coming under surgical treatment, should be fully set forth. After all, this last must be the final test as to what should be and what should not be the actual instruction given on elementary first aid. One must keep in mind the apostolic maxim about milk for babes and meat for strong men. The misapplication of tourniquets is another instance of the saying that "a little knowledge is a dangerous thing."

I am, Sirs, yours faithfully,

Brook street, W., Jan. 21st, 1902. WALTER G. SPENCER.

---

*To the Editors of* THE LANCET.

SIRS,—May I be allowed to indicate some additional defects in "first-aid" instruction suggested by the discussion in your columns on "First Aid for Primary Hæmorrhage: the Wrong Teaching Given to Ambulance Classes"?

In the St. John Ambulance Association's manual, "First Aid to the Injured," 34 pages are devoted to instructing the pupil how to diagnose and to treat various fractures and dislocations. Apparently the pupil is expected, as a result of a course of lectures, to develop into a skilled diagnostician. He, obviously, cannot treat a fracture or a dislocation unless he has first ascertained that a fracture or a dislocation is present. If a surgeon who has had five years' training as a student, not to mention years of actual practice, can often only diagnose these injuries with the aid of a general anæsthetic or the x rays, it is hardly surprising to find that the holder of a first-aid certificate should be unable to make a correct diagnosis, and, if unable to diagnose the injury, of what use is his skill in applying different combinations of handkerchiefs and sticks to suit the particular injury which he imagines to be present?

The time honoured story of the first-aid man who tied up the leg of an unconscious patient with a most artistic arrangement of umbrellas and handkerchiefs prior to removal to hospital, where the house-surgeon found the sound leg encased in umbrellas and the fractured leg looking after itself, is probably a statement of fact. How much better would it be for the injured members of the general public if the first-aid pupil were taught as follows: 1. It is not his business to attempt to diagnose fractures and dislocations. 2. He can do no good and may do harm by manipulating the injured limb. (The manipulations which have ultimately to be made by the surgeon are quite painful enough without subjecting the patient to a preliminary torture at the hands of the first-aid man.) 3. Unless the patient has to be moved from the site of the accident, the right thing to do is simply to support the injured limb in the least painful position, usually the arm in a sling, the leg on pillows. 4. When the patient has to be moved the whole limb should be immobilised, totally regardless of the first-aid man's diagnosis of fracture, dislocation, or other injury.

I should not envy the feelings of the first-aid lecturer who discovers one of his family who has injured a leg being put to considerable pain by the useless, and therefore unnecessary, manipulations of one of his first-aid class in a well-meant attempt to find out "what was the matter"; or even, as advised on page 45, trying to pull the leg into what he imagined to be its "more natural shape." When the manual proceeds to discuss the treatment, based on differential diagnosis, of unconscious patients who may be drunk, epileptic, apoplectic, faint, or what not, the ridiculous side of the question is seen at its best. The half-page of directions for general treatment of insensible patients includes nearly all that is either necessary or useful. Direction No. 2, to lay the patient on his back, is absolutely wrong—he should be laid on his side. If he vomits while on his back he stands a very good chance of sucking vomited matter into his air-passages. Add to the half-page of general directions instruction how to keep the patient warm, if convulsed to prevent him from injuring himself or biting his tongue, if the breathing ceases to perform artificial respiration after clearing the mouth and pharynx, and the first-aid man will know how to do practically all that is called for in the interests of the patient. Plenty of instruction is given in the methods of moving injured individuals, but very little stress is laid on the folly of moving a patient who is suffering from severe shock. The policy of "doing nothing" is not one that appeals to the enthusiastic first-aid man, nor, for the matter of that, to the general public. The two following cases which have occurred within the last 12 months illustrate the prevailing ignorance on this point. A man, severely injured by getting in front of a saluting cannon, was carried half a mile to a medical man's house, where he expired in 15 minutes. An infant, aged nine months, was carried over two miles to a hospital, on arrival at which the state of collapse was so great that it was impossible to think of undressing the patient, who never rallied and died at the end of seven hours. It cannot be too strongly pointed out that, in cases of very severe injury or excessive loss of blood, to carry about a patient, already nearly dead, is simply to obliterate any chance that there might be of recovery. The surgeon must be brought to the patient, not the patient to the surgeon.

Judging from the manual, the first-aid must be able to decide such trifling matters as fracture of ribs, injury of lung, and injury of the various abdominal viscera, including internal hæmorrhage. Arguing from the correspondence on the treatment of hæmorrhage, I expect to be told that for man who attends only one course of lectures such di gnosis is impossible, but for a man who has attended severa courses such diagnosis is simply child's play. It is easy t see why the general public, who are given to understand tha the first-aid man can at once diagnose any of the abov conditions, is apt to condemn as hopelessly incapable an medical man who does not make a diagnosis in five minute The surgeon who is called to an obscure case of injury to th abdomen must often long to be able to make his di gnosis with the ease and rapidity of the holder of a firs aid certificate.

I am, Sirs, yours faithfully,

Plymouth, Jan. 19th, 1902. C. HAMILTON WHITEFORD

---

*To the Editors of* THE LANCET.

SIRS,—May I say a word as an old teacher of "fir aid" on the subject of Mr. W. G. Spencer's letter THE LANCET of Jan. 4th, p. 54? I feel sure a gre deal of the present teaching of first aid is bad *becau it attempts too much.* No doubt the time may con when the explanation of the anatomy and physiology of th human body may be usefully summarised in two or thr lectures. But that day will not arrive until such subjec are taught as they ought to be taught in schools by a course of study and demonstration on dead and living anim tissue. First aid may, however, be learned without attemp ing to explain everything, by an appeal to knowledge whic as matters stand, is really not available. Take the case of

Volunteer Battalion the Gordon Highlanders: Surgeon-Major W. S. Cheyne to be Surgeon-Lieutenant-Colonel.

### VOLUNTEER MEDICAL STAFF CORPS.

*The Glasgow Companies*: Surgeon-Lieutenant D. J. MacKintosh, to be Lieutenant on appointment as Transport Officer. Robert Ramsey to be Surgeon-Lieutenant.

### SOUTH AFRICAN WAR NOTES.

The following have been discharged from hospital to duty: Lieutenant H. F. Hart, R.A.M.C., Lieutenant W. H. Odlum, R.A.M.C., Lieutenant Edward Bennett, R.A.M.C., and Civil Surgeons Kernhoeu and Eustace.

### RECENT DESPATCHES AND THE CONCENTRATION CAMPS.

The extension and development of the blockhouse system, some desultory fighting, with the capture of a few laagers, and the usual sick returns, mainly make up the news from South Africa. It has been a matter of surprise to many people in this country that the Government did not, in the matter of the concentration camps and the alleged ill-treatment of the Boer women and children, seize an earlier opportunity of taking the public into its confidence by intimating the effect of Lord Kitchener's despatches, instead of waiting for the opening of Parliament for their publication *in extenso.* Such a course would no doubt have materially curtailed, if it did not altogether put an end to, the agitation and exaggeration which have been going on of late in this country and abroad. It almost looks as if the Government had cleverly withheld the information in its possession in order to seize upon the most fitting time for publishing it with the best effect, for it is scarcely likely that people would have allowed themselves to be deluded, as they have been, had they known all the facts and how flimsy and insincere was the foundation on which the agitation rested. It was very natural, of course, that public feeling should be greatly touched by the deplorable accounts of the amount of sickness and mortality occurring among the Boer families located in these camps. The publication of Lord Kitchener's despatches describing all that had taken place between him and General Louis Botha and others has, however, thrown quite a new and strong light upon the situation. Mr. Chamberlain had no difficulty in his recent speech in the House of Commons in proving that Lord Kitchener had no option in the matter, but had perforce to adopt the course thrust upon him by the Boer generals in order to prevent the occurrence of still worse evils than those which actually befell the encamped Boer population. The statement of facts regarding the origin and history of these concentration camps set forth in the despatches from South Africa, and so effectively epitomised by the Colonial Minister in his speech, not only afforded a clear account of the nature and causes of the diseases which prevailed, but showed that no effort that humanity could suggest had been spared in trying to deal with the matter. It would probably have proved more merciful in the end, by shortening the course of the war, if the British authorities had altogether refused to undertake the task of rescuing the families forsaken by the Boers and had left them, as any other nation would have done, to their fate. Actuated by motives of humanity those in authority in South Africa could not face the responsibility of adopting such a pitiless course. It is, therefore, illogical and unjust to talk of our "barbarous methods" in connexion with these camps.

### MENTIONED IN DESPATCHES.

In despatches from Lord Kitchener published in the *London Gazette* of Jan. 17th the following names are mentioned: Lieutenant J. M. Sloan, R.A.M.C., for distinguished good service in Colonel Benson's action at Braakenlaagte on Oct. 30th, 1901; Captain G. D. Laing, Medical Officer 5th Imperial Yeomanry, for good service under heavy fire in Colonel Von Donop's action at Kleinfontein on Oct. 29th, 1901; Lieutenant T. E. Fielding, R.A.M.C., for good service at Itala on Sept. 26th, 1901.

Serjeant-Major P. H. Green, R.A.M.C., and Lance-Corporal W. J. Wilson, R.A.M.C., for good work under fire. Lance-Corporal Wilson has been promoted corporal by the Commander-in-Chief.

### THE HEALTH OF THE NAVY.

The statistical report of the health of the navy for the year 1900 has just been issued in the form of a blue-book. It is stated that the returns for the total force serving afloat in the year 1900, after making allowance for exceptional conditions on the Cape of Good Hope and West Coast of Africa and China Stations, may be regarded as satisfactory. The aggregate number of cases of disease and injury recorded for that year furnishes a ratio of 882·29 per 1000, which compared with the ratio for 1899 shows an increase of only 2·66 per 1000 and a decrease of 11·22 per 1000 when compared with the average of the last three years. We hope to deal more fully with the report later.

### REINFORCEMENTS FOR INDIA.

On sanitary as well as upon military grounds the decision of the Government to send seasoned troops from India to replace young soldiers now serving in the South African war seems to be a wise step. According to a telegram from Calcutta it is stated that about 6000 troops, drawn in companies from the various regiments in India, are about to start for South Africa. These men, who are seasoned soldiers, will be replaced by young soldiers now serving at the front, so that there will be no further depletion of the British garrison in India.

### DEATHS IN THE SERVICES

Surgeon-General W. Nash, A.M.S. (retired), late Principal Medical Officer at Netley, on Jan. 19th, 1902, aged 63 years.

## FIRST AID FOR PRIMARY HÆMORRHAGE THE WRONG INSTRUCTION GIVEN TO AMBULANCE CLASSES.

*To the Editors of* THE LANCET.

SIRS,—My former letter on "First Aid for Primary Hæmorrhage," in THE LANCET of Jan. 4th, p. 54, detailed cases such as have been under my own observation. Others have less directly come under my notice and some of your correspondents have confirmed me. I do not know whether the men who made the statements had attended classes held under the auspices of the St. John Ambulance Association or some other. If so, they may never have qualified for a certificate—indeed, have been unqualified "first-aiders." Yet it will scarcely be argued that their notions as regards improvised tourniquets can have been derived elsewhere than from ambulance classes. I have been referred to the "First Aid for the Injured," a copy of which, in its second edition, revised 1901, I have obtained from the St. John Ambulance Association. Examining this authority one finds both in the syllabus for the second lecture of the elementary course of five lectures (p. 7), and also in the text (pp. 76–104), that all the emphasis is laid on arterial hæmorrhage—i.e., the rarest condition of hæmorrhage to which the average pupil will have the opportunity of rendering first aid. The arrest of arterial hæmorrhage occupies 25 pages, venous hæmorrhage receives two pages, and bleeding from small arteries and veins, called "capillary hæmorrhage," half a page and a reference to "wounds." There are 15 figures in the text relating to arterial hæmorrhage, none to impress the mind regarding direct pressure with the hands, &c., for the more frequent kinds. 13 of the figures relate to tourniquets and proximal pressure on the large trunks, the remaining two being a duplicate of the knotted bandage for the scalp.

Why not instruct by concrete examples of arterial hæmorrhages drawn from the more frequently recurring cases in which elementary first aid might possibly render service? A man has cut his throat and just nicked his carotid, or been stabbed above the clavicle and blood is welling up, or the arm has been deeply cut into by machinery, or a butcher's knife has slipped and stabbed him in the femoral artery. Supposing the butcher's boy present at the last accident, he having attended an elementary ambulance class, which sort of instruction would now enable him to do something single-handed? That which has told him to lay the man down, to tear larger the cut in the clothes, to thrust the cleanest cloth at hand into the wound, and then to keep up pressure with fingers and fist until medical assistance comes—or a more elaborate demonstration where the lecturer has the class subject stripped, then one pupil is told off to press on the imaginary wound, a second to control the femoral quite an unnecessary amount from that small fee due to them.

I am, Sirs, yours faithfully,
G. G. GIDLEY.
Cullompton, Devon, Jan. 19th, 1902.

*** Our correspondent, when making his annual return for income-tax purposes, must include his income "from all sources," that from his appointment as medical officer included. He may claim the repayment of the duty deducted by the Post Office authorities (provided, of course, that he has paid income-tax on the return made by him), and should direct his claim for repayment to the Secretary, Inland Revenue (Repayment Branch), Somerset House, W.C. We presume his statement "every Christmas quarter" at 1*s.* 2*d.* in the £ refers to last Christmas only.—ED. L.

## THE SANATORIUM TREATMENT OF CONSUMPTION.

*To the Editors of* THE LANCET.

SIRS,—A few words will suffice in dealing with Dr. Arthur Latham's references to my letter. I am informed that there is nothing to support my "deduction" that a patient must spend two or three years in a sanatorium. I never made it. I merely quoted the words of Dr. Clifford Allbutt *verbatim et literatim* who declared that this length of time was necessary for the obsolescence only of the disease. The attitude of Germany I have (and want) nothing to do with. Suffice it to say that Germany has had 40 years' experience of sanatoriums and has not made the progress we have who have relied exclusively on works of sanitation. Dr. Latham says that I recognise sanitary defects as the main etiological factor in consumption, and yet object to the removal of patients from such debilitating influences to the "fresh air" of sanatoriums. What I said was that, having recognised the cause, you should remove *it* and not the patients. I claim that the money squandered on sanatoriums which could be used for striking at the root of the trouble is badly spent. It may be that these institutions form "only one of the lines along which we have to work," but I have yet to learn that any serious effort has been made by the association at their own expense to clear away insanitary dwellings and remedy sanitary defects. The modern notion is not to trust to tried methods but to convert the earth into a mighty limbo for the aggregation of cases of infective, and so-called infective, diseases the occurrence of which could and should have been prevented. I am sorry I said something which had been already said by Sir John Burdon Sanderson. I tender that gentleman my apologies for having presumed to think in the same grooves as himself.

Now for the "fresh air" of sanatoriums. I regard it as a humiliation that latter-day "scientists" are prepared to do battle for a theory which is consumed at its own focus. The tubercle bacillus is or is not a pathogenic organism. Is it only pathogenic when it is desired to terror-strike governments into the passing of compulsory laws? to obtain powers for the wanton destruction of the country's foodstuffs? to intimidate municipalities? and does its pathogenicity stop at the doors of the sanatorium? Does the *circulus vitiosus* become converted into an angelic halo when once the patient has taken up his abode? I leave Dr. Latham's assertion that in the midst of the coughing and spitting sanatorium crowd there are considerably fewer tubercle bacilli than in an ordinary dwelling to the judgment of your readers. The bactericidal properties of the sunshine which, of course, finds its way into all sanatoriums, even in our *triste* climate during the winter months, prevents the "spread of infection," &c. One wonders if, in addition to forming a corner in fresh air, the association has taken out Royal Letters Patent for the exclusive manufacture of sunshine during the winter months. But this organism, the pathogenicity of which justifies sanitarians in demanding the most preposterous restrictions, leaves the medical and surgical staffs of Brompton Hospital severely alone, although tubercle bacilli are found there in enormous numbers. It does not touch the stationary inhabitants of health resorts frequented by consumptives, although these poor creatures in search of health are hunted from place to place, forbidden to land, and shut out of hotels by the panic-mongering of public health enthusiasts who are supposed to take a kindly interest in their fate. The theory of the infectivity of consumption shares with the "endogenous spore-formation" theory the honour of being a means to an ignoble end. When the assertion that spitting at large constituted a terrible public danger was referred back to the scientists who had proclaimed that exposure to one minute's sunlight killed the tubercle bacillus we were told that the real danger lay not in the bacilli, but in their practically indestructible spores, which delectable theory left a distracted world without means of escape. It was not necessary that these spores should ever have been *seen*. The new method of philosophising is to start a theory and then invent facts to fit it. In the fulness of time somebody had the courage to doubt the existence of these spores, and now the theory is given up. I am advised to apply to one of the London isolation hospitals for a refutation of my argument that aggregation is bad. I shall there learn that "the sequelæ and complications compare favourably with those which obtain in ordinary houses." Secondary infection and post-scarlatinal diphtheria never do obtain in ordinary houses. They are the fruits of aggregation solely. I can assure Dr. Latham that he will have to look beyond these islands—beyond the continent of Europe—before he finds any evidence which will justify the existence of the aggregation hospital.

Now if a patient of the so-called isolation hospital falls a victim to secondary infection during a residence of a few weeks, how shall the sanatorium patient escape who is kept within striking distance of the cause of his disease for two or three years? If the organism does not strike there can be but one explanation, which is that it is powerless to strike and the theory of infection cannot be logically held. To enter into the pretence that there is some skill in sanatorium treatment which cannot be acquired by a man of average intelligence without serving an apprenticeship deserves to be called by a name which describes it passing well.

There is no more need for large "special" hospitals than for "special" physicians. The Nordrach Institution had a world-wide reputation while its construction was primitive in the extreme, consisting of a pair of villas with an old, disused factory as an addendum

A word in conclusion. The profession will do well to adopt an even more cautious attitude than usual towards published sanatorium statistics. We heard the other day of 14 out of 40 sanatorium "cured" patients being dead and one *in extremis* within 12 months of their discharge. The figures were published by patients' friends—not by the authorities of the sanatorium.

I am, Sirs, yours faithfully,
EDWARD DEAN MARRIOTT.
Nottingham, Jan. 16th, 1902.

## "MUNICIPAL AUTHORITIES AND THE FEEDING OF INFANTS," AND "THE INFLUENCE OF MATERNAL FACTORY LABOUR ON INFANT MORTALITY."

*To the Editors of* THE LANCET.

SIRS,—In preparing the numbers of Vol. CLXI. of THE LANCET for binding I notice an annotation under the first of the above headings at p. 608 of your issue of August 31st, 1901, and at p. 814 of that of Sept. 21st, 1901, a letter by the health officer of Norwich (Dr. H. C. Pattin), to which, by your indulgence, I desire to make brief reference. In your annotation you characterise the circulation at Norwich and Darwen of a leaflet on the subject of infant feeding as a "most salutary *precedent*," whilst Dr. Pattin in his communication refers only to those issued at Nottingham, Newington, and by the National Health Society. Permit
to observe that this Norwich "precedent" is (like t
present letter) a somewhat belated one, as for many ye
most excellent leaflets on this subject have been circulat
by the Corporation and Sanitary Association of Manchest
and also by the East London Hospital for Children and t
Liverpool Infirmary for Children. In addition, the Corpo
tion of Stockport in 1899 widely circulated a simi
publication which had been edited by the local medi
society; hence your allusion to the Norwich and Darw
circulars as a "precedent" is unintentionally, but,
viously, inaccurate. Let me also at once say t
I am quite sure Dr. Pattin had no wish to ignore w
has been done elsewhere and was no doubt unaware
it, though in regard to Stockport the facts are alluded to
the *British Medical Journal* of June 2nd, 1900, p 1388, a

bleeding vessel, as Mr Spencer says, why not advise people to stick to local pressure alone as enough for the tyro to learn? or in the case of poisons, without inquiring too particularly as to their exact nature, to emetics? in the case of fractures to immobilising apparatus, and so on? To speak the truth, can any really practical knowledge be obtained without experience? I hold that the converse proposition lies at the root of almost all the useless education of to day.

I am, Sirs, yours faithfully,

Dingwall, Jan 20th 1902 WILLIAM BRUCE

## THE ETHICS OF THE PUBLIC VACCINATOR

*To the Editors of* THE LANCET

SIRS,—In THE LANCET of Nov 23rd, 1901, p 1445 under the heading "The Ethics of the Public Vaccinator," a correspondent states as follows "A public vaccinator can claim no payment for vaccination of persons residing outside his district" Is this a fact? and will you kindly explain the law on the subject?—I am Sirs yours faithfully,

FREDERICK WILLIAM ASHAM

Glasshouse street W Jan 20th 1902

*** The law is contained in Section 11 of the Vaccination Act of 1867 —ED L

## THEATRES AND THE SAFETY OF THE PUBLIC

*To the Editors of* THE LANCET

SIRS,—Amongst all the wise precautions against danger from fire in theatres which are being insisted upon or suggested there is one point, and that the most essential of all, that is persistently overlooked When fire breaks out in a building the most pressing and the most rapidly acting danger of all is that of suffocation Why on earth do not architects and others responsible for the construction of theatres face this question? What is needed is the means of letting out the fumes at or near the roof—in other words, a capacious chimney In a theatre this could be done without extreme difficulty or cost The part of the theatre over the stage rises higher than the auditorium and might on three sides, possibly on four, have large Venetian shutters which, when open, might give some 300 square feet of opening which would allow the fumes to escape and so provide 15 or 20 minutes of safety for the escape of the audience At the same time fresh air would be drawn in over the escaping audience and prove another factor working for safety These louvres should be in charge of a man or men during the whole performance who in case of need could readily open them by means of a lever, and they should be opened for a time after every performance so as to clean out completely the used up atmosphere and thereby add to the comfort and the wholesomeness of the building

I am, Sirs yours faithfully,

Leeds Jan 21st 1902 T PRIDGIN TEALE.

*To the Editors of The Lancet*

SIRS —I see that in a leading article in THE LANCET of Jan 18th, p 173 you say that the London County Council is "determined to check the overcrowding of the gangways of theatres with spectators during the performances" I do not know how long the London County Council has been fired with this salutary resolution, but I think that if any county councillor will go during a performance to any of the London theatres which are doing really well and will inquire for seats in the pit or upper circle or in any of the cheaper parts of the theatre he will get the answer, "Standing room only," or be solicited with the offer of "good standing room" and will find that scores of his fellow citizens are availing themselves of such offers as a matter of course A few weeks ago I was present myself at the first performance of a popular play at the Haymarket Theatre and sat on a step in a gangway crowded to suffocation which I fancy would have become a scene of considerable danger had there been an alarm of fire Theatrical managers naturally do what they are allowed to do in the direction of making money, and I should suggest that the determination of the London County Council will have little result unless it is energetically carried out.

By the way, I was present during part of the Krause trial on Friday last and your recent remarks on the ventilation of the Old Bailey seemed to have had considerable effect The public gallery was nearly empty and so were the gangways The seats were not more than full and windows widely opened at the end of the court opposite the jury box admitted a good deal of fresh air from which unusual intruder some of those persons nearest to it sought to protect themselves by putting their pocket handkerchiefs over their heads

I am, Sirs, yours faithfully,

Jan 20th, 1902 A MEMBER OF THE BAR

## REMOVAL OF THE APPENDIX VERMIFORMIS.

*To the Editors of* THE LANCET

SIRS,—Will you permit me to express my agreement with the arguments of Mr W H Battle in his article in THE LANCET of Jan 18th, p 143, on the advisability of removing the appendix vermiformis after suppuration caused by appendicitis? It is obvious that no surgeon would advocate the removal of the appendix if the mere evacuation of the abscess sufficed to ensure a complete and lasting recovery. Mr Battle's seven cases prove that in many instances the diseased appendix when left behind may not only retard healing but may give rise to dangerous recurrence of the abscess at a later period My own experience is in entire accord with this Although in many, perhaps the larger proportion of appendicular abscesses treated by simple drainage the wound heals and no further trouble results I am convinced that in many cases the appendix left behind considerably prolongs suppuration, retards healing, and remains a source of present discomfort and future danger

The cause of this lies in the frequency with which the appendix contains one or more concretions This is clearly shown in Mr Battle's instructive series of cases I cannot, however, agree with him when he says that "the appendix should be removed as soon as possible after the healing of the abscess" On the contrary, I agree with the contention of Mr J Rutherford Morison that the appendix should be and can be removed in almost every case of suppurating perityphlitis at the same time that the abscess is evacuated Without denying that in some few cases the procedure may be impracticable or unadvisable owing to the general state of the patient, I am convinced by my own experience that in the majority of instances it is neither difficult nor dangerous to remove the appendix in addition to evacuating the abscess at the same operation The main obstacle to this procedure in the minds of surgeons—the risk of infecting the general peritoneal cavity and setting up general peritonitis by breaking down adhesions in the search for the appendix—is more imaginary than real, if I may judge by numerous experiences So long as extravasation of pus into the loin and pelvis is prevented, as it easily can be by proper packing, adhesions may be broken down freely among the coils of small intestine with positive advantage, because pus shut off in separate recesses which would otherwise remain is often evacuated in this way, indeed, in severe cases where the peritonitis is spreading I regard free separation of adhesions and evacuation of pus as the most important part of the operation

I am Sirs yours faithfully,

Wolverhampton Jan 20th 1902, EDWARD DEANESLY

## GENERAL POST OFFICE APPOINTMENTS AND INCOME-TAX

*To the Editors of* THE LANCET

SIRS,—I am holding the appointment of medical officer to the post office here at the usual General Post Office rate, but every Christmas quarter there is a deduction made from the amount in the proportion of *1s 2d* in the £ on the year's gross receipts due to me

I have written various letters to the authorities complaining that as the amount is due as a subscription or club it is in no sense a net profit accruing to me, but nothing has been done in the matter and each year sees the same thing occur Probably you or some of your readers will tell me what is the best course to pursue both for myself and the profession at large for it is certainly unfair that the Government should expect the profession to attend post-office officials (some of whom earn large incomes) at a charity fee and then to deduct essential to the prophylactic action of vaccination since it is by their action that the required area of scarring is produced. If the latter conclusion is the right one, attempts to exclude these micro-organisms from the lymph by treatment with glycerine, and from the skin by aseptic precautions, would tend only to defeat the object we have in view.

I am, Sirs, yours faithfully,
HENRY W. P. YOUNG, M.D., D.P.H. Cantab.
Norbury, S.W.

## "LOOKING BACK":[1] "ON BATHING" THE SKIN AS AN ABSORBENT ORGAN.

*To the Editors of* THE LANCET.

SIRS,—This problem, which was discussed in THE LANCET in 1824, recalls the recollection that it was the subject of my first contribution to medical literature. It was published in THE LANCET in 1839. I was then a student at St. George's Hospital. In a surgical ward a man took a bath containing tartar emetic! This induced severe vomiting. It might be objected that the man swallowed some of the bath-water. I saw no evidence of this, and was satisfied that he had absorbed enough through the skin to cause the vomiting. The case made a lasting impression on my mind as an instructive example of the absorbent property of the skin. It may be regarded as a beautiful experiment, rich in therapeutical suggestions. I have often turned it to useful account in practice.

The eliminating and in-taking functions of the skin, as of other organs—for example, the lungs—are influenced by the balance between repletion and vacuity. Experiments on the absorbent power of the skin must be ruled by this law. If the vascular system is replete absorption is arrested, and inhalation, aerial and liquid, is active. And *vice versâ*, if vacuum is the dominant condition then inhalation or in-drawing is active. It is not a little remarkable that this question of the absorbent capacity of the skin which was discussed in THE LANCET in 1824 should still remain undetermined after 78 years of physiological and pathological observation. The physician has, however, adopted it more or less directly in practice. But the pure physiologist of to-day, if we may take Sir Michael Foster as an authority, still looks doubtfully upon the absorptive power of the skin. He says: "In the case of the sound human skin the balance of conflicting evidence is in favour of the view that soluble non-volatile substances are not absorbed." But surely the problem may be definitely solved by well-directed experiments which take due account of the law that nature abhors a vacuum.

I am, Sirs, yours faithfully,
Jan. 15th, 1902. ROBERT BARNES.

## AN UNUSUAL COMPLICATION OF INFLUENZA.

*To the Editors of* THE LANCET.

SIRS,—In answer to Sir John W. Moore's question in THE LANCET of Jan. 18th, p. 191, respecting "An Unusual Complication of Influenza" which I reported in THE LANCET of Jan. 11th, p. 89, I may say that there was no symptom of typhoid fever, and that the temperature was never above 100° F., and the pulse never above 110.

I am, Sirs, yours faithfully,
J. G. CARRUTHERS, M.R.C.P. Edin.
South Norwood, Jan. 20th, 1902.

## A DANGEROUS PRINCIPLE.

*To the Editors of* THE LANCET.

SIRS,—Continuing the correspondence which has taken place under the above heading in THE LANCET of Dec. 21st, 1901, p. 1764, and Jan. 11th, 1902, p. 121, I beg to trespass further on your indulgence by requesting you kindly to insert the following copy of a letter directed by me to the Under Secretary of State, Home Office, Whitehall, on Jan. 17th, 1902:—

SIR,—I have the honour to acknowledge and to thank the Secretary of State for his letter B37039—8, dated the 16th inst., informing me "that the Council of the Royal College of Surgeons in Ireland allow to Licentiates the privilege of perusing the charters, by-laws, and ordinances, &c., of the College, as printed in one volume, and that" I "have availed myself of an offer of this privilege, but that the Licentiates are not entitled to be supplied with copies of such charters, by laws, &c."

On this ruling of the Council I will only say that it cannot but prove highly inconvenient to such Licentiates as may require professional collegiate guidance outside this portion of His Majesty's kingdom; for instance, in England, Scotland, the Colonies, or British Dependencies.

On the other hand, I beg respectfully to point out to the Secretary of State that in my letter to you [of Jan. 9th] I quoted for his information a letter of the Secretary of Council of the College [dated Jan. 2nd] *addressed to a Fellow* of the Royal College of Surgeons in Ireland, stating "that there are no copies of the by-laws available. A new edition is being prepared, but it will take some time to bring out this edition as several changes are contemplated in the by-laws and charters."

I would also add, in reference to the present attitude of the Council in withholding a copy of the by-laws from the Licentiates, that I hold a communication from the secretary of that Council dated June 21st informing me that "the *revised* by-laws are being printed and as soon as they are ready" I "can have a copy." On June 21st I *was*, and continue to be, a Licentiate. It is evident that since that date the *opinion* of the College as to the advisableness of issuing its by laws to Licentiates has *changed*.

*Respecting the special copy of "charters, by-laws, and ordinances,* &c.," which Licentiates have "the privilege of perusing," I have to observe that I inspected the said copy so far back as Feb. 25th of last year—a date subsequent to the February, 1901, Fellowship Examination—and in May of last year another Licentiate of the College also inspected and took notes from the volume [dated January, 1886] proffered him by the Registrar, R.C.S.I. This Licentiate is prepared to corroborate my statement in the following special particulars.

(A.) In the Charters the following is laid down both in those of 1844 and 85, pages 43 and 59 respectively: "And the examiners, or any number of them declared by the by-law to be competent to transact business as a court of examiners, shall in the presence of the President, or, in his absence, of the Vice-President and two or more Members of *the Council, examine ...... any candidate for a Fellowship."*

(B.) In the by-laws no mention is made in them of the number "declared ...... to be competent to transact business," unless an "educational ordinance" or other "ordinance" can be regarded as such. These, however, are printed in the volume referred to as a class of rules, differing from by-laws, and I should imagine if they have not received the sanction of the Secretary of State as required by the Charter of 1844, or the sanction of the Lord Lieutenant of Ireland as required by the Charter of 1885, they cannot be regarded as by-laws. (There is no evidence of such sanction.) In fact, pages 62 to 66 are specifically intituled on each page as "By-laws," and under the heading of the title "By-laws of the Royal College of Surgeons in Ireland" (page 62) may be read "which have received the approval of the Queen *in conformity with last Clause of Sec. 7 of Supplemental Charter."*

(C.) In the Ordinances it is true the number of examiners is laid down.

(D.) In the Educational Ordinances the following appears at page 106 of the volume:—

FELLOWSHIP EXAMINATIONS.

"*Presence of Councillors:* The President or Vice-President and two Members of Council shall be present at the Oral Examination," &c. My contention, therefore, is that the President, Vice-President, and Council of the Royal College of Surgeons in Ireland at the Ordinary Fellowship Examination of February, 1901, did not observe their charters or their by-laws if it be conceded that the educational ordinances can be classed as such, and I would respectfully urge upon the Secretary of State to give me the reply to my letters of Dec. 9th and 14th, *in which I ask specifically if the corporate body* concerned deny the accuracy of my statement that the witnesses prescribed were not present on the occasion stated. I subsequently referred to this question on Dec. 18th as being not a *personal* but a *constitutional* one, and I *contend that it is made in the* best interests of the College itself and of the vast body of Fellows and Licentiates which it is empowered by the Crown to make and to control.

I have the honour to be, Sir, your obedient servant,
S. WESLEY WILSON.

P.S.—Kindly see affidavits sent Oct. 22nd: (*a*) As to non-observance of charters; (*b*) method taken by a Fellowship Examiner to procure Fellowship candidates for his son's tuition.—S. W. W.

My apology is due to you for thus far trespassing on your space, but I do so that the profession generally will recognise the justice of the claim that Licentiates have privileges which must not be foregone by a corpora licensing body, however strenuously such corporate bo may endeavour to ignore the fundamental principles of i existence and the legal carrying-out of functions for whi it is responsible to the State.

I am, Sirs, yours faithfully,
Dublin, Jan. 18th, 1902. S. WESLEY WILSON.

## BEEF WORM IN THE ORBITAL CAVITY

*To the Editors of* THE LANCET.

SIRS,—In the account of his case of Beef Worm in t Orbital Cavity in THE LANCET of Jan. 4th, p. 19, Mr. T. W. Gann is under the impression that the case is unique. M I be allowed to draw his attention to an almost identical ca already recorded (with very instructive illustrations) by I Fred. Keyt, assistant colonial surgeon, British Hondura a colleague in the same colony and in the same service Under the circumstances it is singular that this earli also in a prominent leading article in the same journal of July 7th, 1900, p. 38, on "Infant Feeding and Maternal Education," as well as in *Public Health* for February, 1901.

---

[1] THE LANCET, Jan. 4th and 11th, 1902.

[1] Vide Brit. Med. Jour., Feb. 10th, 1900.

In reference to this question of maternal education, I think it is due to the progressive Corporation of Stockport to place prominently and distinctly on record to its credit the fact that it is the first and only body that has hitherto attempted to grapple practically with the question, as at the discussion on Infant Mortality at the Cheltenham meeting of the British Medical Association the teaching of infant hygiene was advocated by more than one speaker without any reference to the fact (of which at least two of them were fully aware) that such instruction was already being systematically given in the elementary schools at Stockport. On Feb. 1st, 1900, the teachers of that town, together with one of H.M. Inspectors of Schools (*Mr. F. T. Howard, M.A.), met the sanitary committee by invitation, and the outcome of the conference was that the teachers unanimously agreed to arrange for the* instruction of the elder girls in the feeding and management of infants, using as their guide a booklet (copy herewith), drawn up at their request by the writer and supplied by the sanitary committee. The committee also offered a money prize to each school in which the subject was taught, and supplied approved forms of feeding-bottles, &c. A trained health visitor was appointed who visited each school occasionally to supplement by demonstration and otherwise the instruction given by the regular teachers. My successor (Dr. Meredith Young) states that the system thus *inaugurated works excellently, and personally testifies to the* soundness and satisfactory result of the teaching, whilst the sanitary committee is not a little proud of the real "precedent" which its action has furnished.

I further desire to refer to Dr. G. Reid's suggestion[1] that mothers should not be allowed to return to work in factories for at least three months from the date of their confinement, as they would then probably suckle their babes till the most precarious period of life had been tided over. In Stockport, where the infant mortality was very excessive, I found on personal analysis of 5101 deaths of infants during 1890-99 that as many deaths (one-fifth of all) took place in the first month of life as in *the second and third together, whilst three-fifths of all* occurred during the remaining nine months, these figures closely conforming to those at pp. 11-17 of the Registrar-General's Annual Report for 1891. Having regard to the food- and comfort-yielding value of the mother's earnings, is it, therefore, worth while to advocate a measure that cannot possibly benefit four-fifths of the infants that at present die? And has it ever occurred to Dr. Reid that such prolonged idleness would inflict great and useless hardship on a large number of mothers whose *infants die within* a few days of birth, or long before the expiration of the suggested three months? Is it not, moreover, a fact that in 1893 or thereabouts a special sub-committee of the Council of the British Medical Association found itself unable to recommend this measure and that after careful inquiry by the Home Department the then Home Secretary (Mr. Asquith) decided against it? Judging from the enormous number of deaths from "prematurity," "low vitality at birth," &c., as well as from personal knowledge of the conditions of factory life, *I am inclined to think that any* legislative change, if such be practicable, should be in respect of pregnant women who often continue to work in the mills almost to the *hour of their confinement.* With regard to *crèches,* which Dr. Reid also recommends, they have been tried with most intensely disappointing results in Liverpool and other places, for the simple reason that mothers will not use them, preferring to pay as much as 4*s.* per week to some ignorant neighbour to look after their babes. The strict enforcement and extension of the Infant Life Protection Act, together with the instruction of those who in the near future will become mothers, seem to be the most hopeful means of dealing with this national evil Apologising for the length of this communication on a subject which has for many years been of special interest and official importance to me,

I am, Sirs, yours faithfully,
CHARLES PORTER,
County Medical Officer of Shropshire; late Medical Officer of Health of Stockport.

Shrewsbury, Jan. 14th, 1902

⁂ Dr. Charles Porter encloses some admirable leaflets dated 1899 and a pamphlet dated 1900. The word "precedent" was obviously incorrect and we think it well to apologise in advance to any municipality that may have issued leaflets previously to the sanitary authorities of Stockport.—ED. L.

# THE RELATION OF THE CHURCH TO SANITARY REFORM.

*To the Editors of* THE LANCET.

SIRS,—The suggestion of "Vicar" in THE LANCET of Jan. 18th, p. 192, is most valuable—viz., that the edge of the chalice at the celebration of the Holy Communion should be wiped with a fair linen cloth between each administration. It will, I hope, become universal. Although the use of separate cups would, of course, absolutely eliminate the dangers of infection, yet it is extremely improbable that such a custom would ever find favour except among very few—in fact, though it is now some two or three years since the idea was suggested I have never heard of its being adopted except in a very few Dissenting places of worship. Rightly or wrongly, the "usages" of churches of the Establishment are governed mostly by tradition—*ancient in all cases and in some supposed to be primitive*: tradition first, sanitation, or what you like, second. Witness the almost unanimous opposition of the Church to cremation Moreover, in many churches, and not only in those of the most "advanced" type, it is the custom for the celebrant not only to consume the wine that may be left, but also to rinse the emptied chalice and drink the rinsings—so great is the veneration (and surely no charitable person would sneer at it) in which the consecrated elements are held. How could this be done with a multitude of little cups?

I am, Sirs, yours faithfully,
Wherstead Vicarage, Ipswich, Jan. 20th, 1902. R. A. L. NUNNS.

# THE ESTIMATION OF THE EFFICIENCY OF VACCINATION BY THE SCAR AREA.

*To the Editors of* THE LANCET.

SIRS,—The method of estimating the efficiency of a vaccination by the area of the scars produced seems to me unsatisfactory for the following reasons. By employing an aseptic lymph and by taking rigid precautions against sepsis throughout the course of the vaccinia, it is, I believe, possible to obtain good vesicles which will dry up without ever becoming pustular and which will leave hardly any scar at all. *Results approximating this ideal I myself have obtained* in a considerable number of cases of secondary vaccination by the following method. The operation having been performed with the usual aseptic precautions, a dressing of dry boric acid lint was applied and fixed with strapping. At the end of six days or a week, when the vesicles were well developed, this dressing was removed, the arm bathed with antiseptic lotion, and a dry dressing of bicyanide gauze applied. When examined about 10 days later the pocks would be found to have scabbed over, the scabs being adherent to the gauze. It was then only necessary to cut the gauze so as to leave a circular piece adherent to each scab. *When the latter fell off in the ordinary way it left* only a very small scar indeed. In one case, for instance, although large vesicles developed, the spots when examined two months after presented small patches of hyperæmia not more than a third of an inch in diameter in which four or five little areas of scar tissue of about the size of a pin's head could be seen.

If, on the other hand, vaccination is performed without any special aseptic precautions the vesicle will become a pustule, the pustule an ulcer, a considerable portion of the corium will be destroyed before healing takes place, and thus a large scar will be produced. Now, I take it, that all bacteriologists will admit that pustulation is effected by the entry of pyogenic organisms into the vesicles. It appears to me, therefore, that the size of the resultant scar in vaccination depends almost entirely *on the extent to which these* organisms have been at work. I am thus driven to one of two conclusions, either that suppuration in the vesicle is not an essential of vaccinia, but is merely the result of sepsis and that, therefore, a large scar is of no value except as evidence of insufficient care, or that the action of pyogenic organisms is have fully appreciated the conditions of the appointment, they wish before inviting your attendance to make it clear to you that this appointment will require you to pay visits to schools for 400 school sessions from 9.30 to 12 and from 2 to 4.30, together with the digesting of the information and the drawing-up of reports concerning such visits in the time outside school hours.

---

[1] THE LANCET, August 24th, 1901, p. 549.

The committee might be willing to allow this work to be spread over two years, instead of one year, if you are unable to give up so much time as the 400 visits in one year would require, but they wish the work to be finished in one year if possible, and they would prefer to make the appointment in such a case for one year only, offering a remuneration of 50 guineas for the payment of such 200 visits. If you are still an applicant for the post of oculist under the conditions as above explained they will be glad if you will appear before the sub-committee on Tuesday, Jan. 28th, 1902, at 11.30 A.M.

Faithfully yours,
For G. H. Croad, Clerk of the Board (H.S.W.).

# THE DESTRUCTOR NUISANCE AT TORQUAY.

(By our Special Sanitary Commissioner.)

---

### The Inhabitants Petition for an Investigation.—The Explanations given by the Local Authorities in answer to the Complaints.

A considerable number of the inhabitants of Torquay have complained bitterly of the nuisance occasioned by the refuse destructor recently built in that town. After many endeavours to obtain from the town council an abatement of this nuisance a petition was sent to The Lancet which was drawn up in the following terms:—

> We, the undersigned inhabitants of the borough of Torquay, injuriously affected by the smoke fumes and gases ejected from the refuse destructor and having after repeated efforts failed to obtain from the town council the promise of adequate remedial measures, respectfully petition the Editors of The Lancet in the public interest to send a commission to inquire into matters so vitally affecting the health of Torquay and to point out what measures must be taken to safeguard the purity of the air.

This petition bore 70 signatures, including the names of several medical men and prominent residents, and more signatures, it was stated, could easily have been obtained if more time had been devoted to collecting them. Some of the signatories declared that they would willingly have removed to another quarter or to another town, but, having purchased their houses or rented them on a long lease, they were unable to do so. They protested that their health was seriously affected, and they were convinced that this was due to the destructor, because they had not suffered in that manner before the destructor was built, and they recovered whenever they were able to live for a short while elsewhere.

Before dealing in detail and at length with these complaints and attempting to describe the problem at issue, it is only fair to give what may be called the official version of the question. In this the mayor, the chairman of the Destructor Committee, and the borough surveyor very courteously afforded me every facility. From the borough surveyor, notably, I was able to obtain the history of what had occurred. Thus, I was informed that up to the year 1895 the household and garden refuse used to be carted away to various "tips." The principal deposit or "tip" was just beyond the former borough boundaries at Windmill Hill. This is inland and to the north of the town. There was a secondary "tip" in a much more central position, close to the Torquay General Hospital and in the valley that divides the town in half. To the south-east and on the outskirts of the town there was another "tip" where the refuse was readily disposed of for use in the kitchen-gardens. Cartloads were sent to anyone who could utilise the refuse as manure for gardens. These persons had themselves to sort out the "hard core"—that is to say, the broken galley-pots, tins, and other hard substances, which they threw over the cliffs or on to any convenient waste land. As for the waste-paper, it was gathered together in a heap to await the dispersing effects of the next gale. There were also a number of smaller "tips" in different directions, and there is no knowing how long this very simple manner of dealing with a very complex problem might have continued but for the action of the Local Government Board. In 1895 this authority insisted that the Marychurch Urban District Council must build an isolation hospital. Thereupon a site was selected for the proposed fever hospital close to the main "tip" at Windmill Hill. It was then estimated that there were on this spot some 10,000 cartloads of decomposing town refuse. This was an immense heap and its proximity to a hospital could not be tolerated. Complaints were made also in regard to other, though minor, "tips" which were likewise in the Marychurch district. This raised a very nice point of law. Torquay is wedged in between two rural districts. Where was the refuse to be deposited if it was refused by these two districts? and had the fact that the "tips" had been sanctioned for many years established a right to continue using them? The refuse could not be left in the streets of the town. But the Marychurch authorities urged that they were prevented from building the hospital they had been ordered to construct. They called upon the Torquay Town Council to abate the nuisance, and they declared that the whole of the district round the main "tip" was inaccessible in consequence of the stench and the legions of rats that bred and flourished on the refuse depôt. These verbal protests were followed by an official notice which was served on the Torquay Town Council on May 11th, 1896. By that time the Torquay sanitary authorities had already ceased to take refuse to Windmill Hill; but they were now called upon to remove the great heap that had accumulated. Again, it was a moot question as to whether, after having allowed the depôt to be made, there existed any legal right to enforce its removal. This was indeed an embarrassing situation. Emissaries were despatched far and wide to persuade the farmers in the surrounding rural districts to come and to fetch the refuse away as manure. Here and there a farmer availed himself of this offer, but this help was very limited and insufficient. Fortunately there was close at hand a brickfield, and the owner offered to allow a claypit to be filled up with the refuse if it was subsequently covered over with two feet deep of earth. This was done and the Windmill Hill refuse-heap was completely removed, so that the difficulty with the Marychurch authorities was overcome.

At Torquay, however, the refuse continued to accumulate, and, if the mischief which had been done in the past had been remedied, there was no provision for the future. The "tips" that remained, especially the one in the valley near the Torquay General Hospital, were badly situated and altogether unsuitable, but no other and better sites could be obtained. Thereupon a series of ardent discussions were held by the Torquay Town Council which resulted in the conclusion that there was no other method of disposing of the refuse than by fire. Having thus agreed on the general principle it was almost as difficult to determine which of the many and rival destructors was best suited for the purpose in view. A travelling committee was therefore appointed to see what had been done elsewhere, and they went to Bournemouth, Southampton, Eastbourne, and to several Lancashire towns. These inquiries resulted in the preference being given to the new Warner high temperature destructor, and a scheme was devised forthwith for the building of a destructor on this system, with six cells or chambers. Then commenced the battle of the sites. 20 different sites were selected and proposed and it was most difficult to decide where the destructor should be put. All these matters had taken two years to debate. As the claypit by the brick-kilns was rapidly filling up something must be done. One by one the various sites proposed were eliminated and eventually a site was selected at Upton, in the direction of Windmill Hill but somewhat nearer to the town, and in October, 1896, the specifications were approved. The next month tenders were invited from two firms and elaborate schemes were sent in, but they were all too expensive. Then it was resolved to reduce the size of the destructor from six to four cells. Messrs. Goddard, Massey, and Warner undertook to build a destructor which would consume eight tons of refuse per 24 hours in each cell, or 32 tons in the four cells. As at that time only about 20 tons were collected in the course of a day this allowed a margin of 12 tons for the future extension of the town. For actual needs only three cells were necessary.

Having thus at last fully matured its scheme the Torquay Town Council now applied to the Local Government Board to sanction a loan of £6500 for the building of the destructor. In January, 1897, the Local Government Board sent Colonel A. G. Durnford, R.E., to hold a public inquiry previously to assenting to the loan. The town clerk then explained that, if properly worked, the destructor would cause no nuisance whatsoever. It was true that a memorial signed by 50 owners and occupiers objected to the site selected; but this did not mean much, for the majority of the signatories resided at a considerable distance from the proposed site. In the *Torquay Directory and South Devon* record should have escaped Mr. Gann's observation, but, of course, allowance must be made in such matters for the exigencies of "bush life." There is, however, I fear, a growing tendency on the part of some to ignore the work of others. This may be due to the number and voluminous character of our works of reference, to which the pressure of work makes it impossible for many to refer. But one cannot help lamenting this tendency to overlook or ignore the painstaking work of others, not alone because one likes to see credit paid where credit is due, but because one is loth to see the fairer courtesies which always existed between members of our profession in danger of being brushed into oblivion. Thus a noble calling may soon degenerate into a "pushful" profession.

I am, Sirs, yours faithfully,
GEORGE FERDINANDS, M.D. Aberd.

Aberdeen, Jan. 8th, 1902.

## CANCER AMONG HINDOOS.

*To the Editors of* THE LANCET.

SIRS,—With reference to Mr. C. B. Keetley's letter in THE LANCET of Jan. 18th, p. 192, on this subject I append the names of the three or four accredited booksellers in London from whom the annual reports of the medical institutions of India may be obtained. Mr. E. A. Arnold, 37, Bedford-street; Mr. B. Quaritch, 15, Piccadilly; Messrs. Constable and Co., 2, Whitehall-gardens; Messrs. Sampson Low and Co., St. Dunstan's House, Fetter-lane; Messrs. Luzac and Co., 46, Great Russell-street; and Messrs. Kegan Paul, Trench, Trubner, and Co., Charing-cross-road.

I hope this will partly mollify Mr. Keetley. As I am on the eve of leaving for India and have none of my works of reference at hand I am unable, except on my own *ipse dixit*, to give him the proper and more scientific—*ergo*, more up-to-date—definition of the word "Hindoo." On my arrival at my destination in Madras I shall, if the subject is still open in your columns, remedy my present inability.

Do not any of Mr. Keetley's dictionaries (those of an encyclopædic character) clear up the point "whether the Mahomedans circumcise or not"?

I am, Sirs, yours faithfully,
C. DONOVAN, B.A., M.D., B.Ch. R.U.I.,
Captain, I.M.S.

Instow, N. Devon, Jan. 21st, 1902.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of Jan. 18th, p. 193, I notice a statement to the effect that Jews are less prone to cancer than other civilised peoples. This statement is certainly erroneous so far as the Jews in the United States are concerned; and it seems to me that the balance of evidence is against its acceptance as applied to most other countries. Dr. Billings' statistical reports show that in the United States the Jewish mortality from cancer is almost the same as that of the rest of the white population. He gives the cancer mortality per 1000 deaths for Jews and Gentiles as follows:—

| | Jews. | Other U. S. Whites. |
|---|---|---|
| Males ... . ... .. | 13·58 ... ... ... | 13·09 |
| Females.. .. .. | 21·65 ... ... ... | 23·59 |

It was the opinion of the late Sir B. W. Richardson—who had considerable experience among London Jews—that they were as prone to cancer as other London people. Billroth's experience in Vienna and elsewhere coincides with this. Moreover, from observations made by Bauby in the neighbourhood of Toulouse, it appears that pork-eaters are no more prone to cancer than those who feed on other kinds of meat.

I am, Sirs, yours faithfully,
Clifton, Bristol, Jan. 18th, 1902. W. ROGER WILLIAMS.

## IS SALT A PROBABLE CAUSE OF CANCER?

*To the Editors of* THE LANCET.

SIRS,—The interest which has been created by the publication in your influential paper of Dr. James Braithwaite's theory with regard to salt being a cause of cancer has been very marked, and as a number of other newspapers have commented on the subject the idea seems to be gradually spreading abroad that what has hitherto been considered and proved to be a wholesome and necessary article of diet is in fact a thing to be shunned and avoided as dangerous. Dr. Braithwaite says the idea originated in his mind by his noticing the comparative immunity of the Jews from this disease, and explains it by the difference in their diet, which he says consists mainly "in the absence of bacon and ham from the diet of the Jews."

I think all your readers must admit that Dr. Braithwaite in his very interesting paper has conclusively proved that in those sections of country where a very large amount of bacon and ham is consumed the disease of cancer is most prevalent, and I merely write to suggest that it is possibly not the salt, but the unclean bacon and ham, that is responsible for the scourge, and as I have lived on the other side of the Atlantic for a number of years and know something of the manner in which pigs are fed over there I cannot see how it can possibly be otherwise. The greater part of the bacon and ham consumed in this country is imported from the United States and Canada, and it is a notorious fact that at many slaughter-houses in those lands the pigs are habitually fed on the entrails and blood of slaughtered animals. Unfortunately, owing to a very imperfect system of cattle inspection, some of the cattle which are killed there are infected by diseases of a cancerous nature, and if the pigs are fed upon the entrails of such animals it follows that their bodies are likely to become impregnated with the effects of such a diet, and if Englishmen persist in eating the flesh of such a carnivorous animal so impregnated they will probably reap the consequences, while the Jews who refuse to eat such food will naturally be exempt from such disease.

In the Revised Statutes of Ontario, chap. 248, sec. 108, the sanction of the Provincial Government is given to the feeding of pigs with blood, offal, and the meat of any dead animal, but the Act provides that they must not be fed on *decomposed* or *putrid* blood and offal, and that these must be steamed before feeding the pigs. It further provides that if the medical health officer discovers that the pigs have been fed upon putrid offal, then he has power to destroy such pigs so as to prevent them from being used as food for man. It is not a place, however, where the medical health officer likes to spend much of his time and therefore the inspection is not very rigid. It has become rather fashionable in recent years to impugn the accuracy of the Bible in many respects, but those portions of it which call our attention to the inadvisability of indulging in swine's flesh may be well worthy of consideration in the light which has been thrown on the subject by the statistics in Dr. James Braithwaite's exhaustive paper. Any information which may be the means of putting us on our guard against this terrible disease must be hailed with satisfaction.

I am, Sirs, yours faithfully,
Hanover-terrace, W., Jan. 22nd, 1902. R. D'OYLY NOBLE.

## MEDICAL APPOINTMENTS UNDER THE LONDON SCHOOL BOARD.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of Dec. 14th, 1901, p 91, the London School Board advertised for "two oculists (of either sex) for the purpose of testing the eyesight of the children in the senior departments of the schools of the Board and for giving such advice and taking such steps thereon as may be desirable." The salary offered was 100 guineas and the work was expected to be completed in one year. The statement of duties expected being a little vague, I therefore wrote for further details. In reply regret was expressed that no further details could be given. I sent in an application with required testimonials and references. After some days I received the inclosed letter which, I think, might be of interest to the profession. Evidently experience is not considered a necessity, or such a handsome remuneration for so much important work would not be offered, seeing that practically all one's time would be required to carry out the duties.

I am, Sirs, yours faithfully,
Jan. 18th, 1902. A RETIRING CANDIDATE.

[INCLOSURE.]

SCHOOL BOARD FOR LONDON.
Victoria Embankment, W.C., 17th January, 1902.
POSTS OF OCULISTS.

DEAR SIR (OR MADAM),—I am directed to state that the committee have favourably considered your written application, but as they think it possible from your standing in your profession that you may not increase in the building of new houses close to the destructor. Since the selection of the site for the destructor 100 cottages have been built within 400 yards and the St. James schools which are also close at hand have likewise been erected after the destructor. Consequently, it is maintained that the complaints are greatly exaggerated and sometimes purely imaginary, and that when they have been partially justified this has been due to the imperfect working of the destructor, and that imperfections of this nature can and will be rectified. Such, as far as I was able to ascertain, were the main arguments brought forward in defence of the destructor. These, however, represent but one side; it will now be necessary to consider what is said on the other side and to examine in detail the complaints made.

(*To be continued.*)

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

### *The Plague Epidemic: A General Increase.—Plague Vaccine.—The Reconstruction of Bangalore City.*

THE last plague returns show 9198 deaths throughout India for the week ending Dec 21st, as against 7795 in the week preceding, and 2267 in the corresponding week of last year. The principal figures are: Bombay districts, 5274 against 4735; Punjab, 1914 against 1685; Mysore State, 533 against 404; Madras districts, 324 against 233; Bengal, 327 against 291; and North-West Provinces and Oudh, 176 against 228. It will be seen that all the districts, with the exception of the last, return an increased mortality. Kashmir returns 361 deaths for the fortnight, and Bombay city reports on Dec. 31st for the previous week 180, an increase of five on the previous week. Calcutta also reports an increase, 28 deaths being returned for the week ending Dec. 28th as against 15 for the previous week. Since the general returns were published a further increase is reported from the Punjab, especially in the districts of Jullunder, Hoshiarpur, and Sialkot. A fresh province, the Nabha State, is now infected and returns 124 deaths. For some reason or other Poona city is left out, and yet we know from the local press that a large number of deaths are occurring in the city daily. Karachi had 54 deaths and Hyderabad State 55 A case of plague has been discovered in Madras city, which has up till now been free. These returns are very ominous, as the increase is general, and in several districts where plague raged last year a recrudescence seems imminent About this time last year the disease developed in Calcutta, so that it is only to be expected that a decided increase will show itself shortly. Bombay city also shows signs of another recrudescence.

In the week ending Dec. 27th 40,081 doses of plague vaccine were sent out from the Research Laboratory in Bombay.

As the result of plague the city of Bangalore has been largely reconstructed. Of the 10,800 houses 1922 have been demolished Five and a half miles of new streets have been made. The southern extension, chiefly to be occupied by Hindus, is laid out in the form of a rectangle with an open space in the middle of 22 acres which will be used as a public recreation ground, and the houses around run north and south and east and west in parallel lines. In addition there are reserved two other open spaces of six acres and nine acres in area respectively This settlement is divided up into eight blocks, each block being reserved for members of a particular section of the community. The chief roads—viz., approach, boundary, and diagonal—will be 100 feet wide. The population will amount to 31·8 per acre. In the rear of each row of houses there will be a conservancy lane. It is reported by the superintending engineer that "for symmetry, regularity of street frontages, for accessibility by the shortest routes, for air spaces and for public squares, for convenience of conservancy and for perfect drainage they can only be equalled by some of the most recent cities of America." The northern settlement has been very similarly planned. The total cost to the State has been less than six lakhs and when all the sites have been sold the net cost will hardly exceed two lakhs. This is a splendid example for other Governments in India to follow.

**Jan. 3rd.**

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *The Proposed University for Liverpool.*

A DEPUTATION of governors and members of the Senate of University College, Liverpool, consisting of Sir John Brunner, Bart., M.P., Sir Alfred L. Jones, K.C.M.G., Mr. A. F. Warr, M.P., Principal A. W. W. Dale, Professor Rubert W. Boyce, Mr. E. K. Muspratt, Mr. W. E. Willink, and Mr. J. W. Alsop, waited upon the Lord Mayor on Jan. 13th and presented him with an influentially signed requisition to convene a meeting at an early date to consider the desirability of establishing a university within the city of Liverpool "for the advancement of knowledge and for the diffusion and extension of arts, sciences, and learning." Among the signatories to the requisition were the Earl of Derby, K.G., the Lord Bishop of Liverpool, and Mr. William Rathbone, formerly M.P. for Liverpool. The Lord Mayor has fixed Monday, Jan. 27th, for the meeting to consider the subject of the said requisition.

### *The David Lewis Northern Hospital.*

At the annual meeting of the trustees of this hospital held on Jan. 15th the retirement of Mr. Chauncy Puzey, the senior honorary surgeon, was announced. Mr. Puzey retires in accordance with the law of the hospital regulating the term of office of the honorary medical staff. The chairman expressed the deep regret of the committee at Mr. Puzey's retirement, and in recognition of its high appreciation of his valuable and self-sacrificing services for the past 26 years recommended his election by the trustees as a member of the committee in addition to the post of honorary consulting surgeon. It is a pleasing fact to record, in view of the recent trouble at Macclesfield, that the relations between the committee and the medical staff of the David Lewis Northern Hospital have always partaken of the most cordial character. Among other matters of interest noticed by the chairman were the usefulness of the apparatus for the treatment of lupus, kindly provided by Mr. Benn W. Levy, which had been doing such excellent work that it had become necessary to instal a second lamp, for which Mr. Levy had made himself responsible, and he has kindly promised to bear the whole cost of working the apparatus for another year; also the amount of good effected by the horse ambulance, now in charge of the corporation, which had been called out 1016 times during the year. The ordinary expenditure had been £9543 as against £7956 in 1900. There was a balance of £4425 due to the bankers of the charity. The receipts from all sources had been £10,153; including £1943 from the ex-Lord Mayor's Hospital Century Fund and £1742 from the Hospital Saturday and Sunday Fund. 1801 patients were admitted to the hospital during the year 1901, whilst there had been 8954 out-patients, involving 26,540 attendances.

### *Malaria on the West Coast of Africa: Newly Discovered Parasite.*

Sir Alfred L. Jones, K.C.M.G., the chairman of the Liverpool School of Tropical Medicine, has received from Major Ronald Ross, F.R.S., late I.M.S., who is directing the malaria expedition of the Liverpool School of Tropical Medicine which is now engaged in investigations on the West Coast of Africa, the following message: "I have great pleasure in informing you that Dr. Dutton has made a very important discovery at Bathurst. He has found a new kind of parasite which causes fever in human beings The parasite is like the one which causes the fatal tsetse fly disease among horses in South Africa."

### *The Home for Epileptics at Maghull.*

In THE LANCET of June 29th, 1901, p. 1865, allusion was made to the generous offer of Sir Alfred L. Jones, K.C.M.G., to contribute the sum of £1000 towards the funds of the above institution, on condition that a further sum of £9000 be raised within six months from the date of his offer (June 22nd, 1901). The £10,000 were required to purchase and to equip a farm for the employment of male patients who had been trained to regular work at the "home." The six months expired on Dec 22nd, 1901; and it has come out that £8175 have been promised. This amount is £825 short of the sum stipulated upon by Sir Alfred L. Jones, but, with his usual generosity, he has kindly consented to extend

*Journal* of Jan. 20th, 1897, a report is given of the Local Government Board inquiry, and this local paper states that :—

> So convinced was the council that no nuisance would arise that, subject to a clause in the contract, it had taken upon itself all responsibility. The clause provided that the contractors should be held answerable for the efficient working of the destructor for the first 12 months.

The borough surveyor, Mr. H. A. Garrett, is reported to have said that the chimney would be 150 feet high, and if the stokers did their work properly there would be no nuisance. He stated that there had not been a single complaint from the inhabitants of the houses situated close to the Bournemouth destructor. Mr. Warner supported this view by explaining that he had been connected with the erection of from 300 to 400 destructors. Then, alluding to the spot selected at Torquay, he is reported to have said that :—

> The site proposed was the most favourable one which he had ever seen and his firm was quite prepared to indemnify the council for 12 months. They had erected destructors immediately adjoining house property, but had never received complaints after erection, although there were many before. At Buxton the destructor was close beside a favourite walk, while at Hornsey it adjoined the works of the New River Water Company.

Mr. Warner added, when alluding to the apprehensions of neighbours, that he felt "convinced that there would be no cause whatever for complaint." Mr. Harris, however, who owned property at Upton, presented a memorial signed by 32 ratepayers protesting against the site selected, but the town clerk replied that there were 719 ratepayers in the district in question.

In the face of such evidence it is not surprising that the council should have entertained no apprehensions as to the unsuitability of the site proposed. Though it is, perhaps, easy to be wise after the event, still I must confess to great surprise in reading this evidence. It is considered necessary to build high chimneys to destructors; but what is the use of a high chimney if the destructor is placed at the bottom of a valley? Either the combustion is so perfect that a high chimney is not necessary ; or, if it is necessary, then it ought to be considerably above the level of inhabited houses. But if a destructor is built at the bottom of a valley then the top of the chimney may be on the same level or even on a lower level than that of the houses erected on the surrounding hills. It seems only logical to conclude that if a lofty chimney has to be built so also should an elevated site be selected and there was such a site close to the valley that was chosen in preference. This is known as the Stantaway rock and is situated to the north-east of the Upton valley. There was also another elevated site to the north-west. But the objection was raised that if the destructor was built on the top of the hill it would be seen from all directions and would constitute an eyesore. As it is it must be confessed that the destructor has been very discreetly hidden and that it is more readily smelt than seen. The consideration which probably had the most weight in favour of the actual site is that it can be approached by six different roads. The refuse can be brought to this point in direct line from the various districts where it is collected ; whereas, in the case of many of the other sites which were suggested it would have been necessary to cart some of the refuse through several districts before reaching the destructor. As for the two hills, there is but one road leading to the Stantaway rock and two roads to the other hill, and, of course, the drawing of the refuse up a hill would involve extra expense in cartage. Altogether, therefore, if it be a fact that destructors create no nuisance whatsoever, then doubtless the site selected was the most convenient available. Evidence was adduced to show that persons living close under destructor chimneys had not complained ; but I would urge that what was wanted in this case was evidence to show that people could live on the same level as the top of the chimney without being inconvenienced. Such, however, were the reasons given for the selection of what appears to me to be a very unsuitable site.

The Local Government Board having given its assent to the loan the destructor was built and was ignited for the first time in September, 1898. At first, however, no refuse was destroyed. The object was to dry the brickwork and for this purpose only firewood was burnt. Yet, I was told, a week had not elapsed before a lady living in the Tor district wrote to the town council complaining that she was being poisoned by the refuse fumes. No refuse had been burnt, and, indeed, it was not till two months later that the full capacity of the furnaces as refuse destructors was put into action. This incident shows the power of suggestion, and this, no doubt, has played an important part in the complaints which have been made. At first there were, however, no further protests. But in the course of time a person who was building houses in the neighbourhood began to complain and soon many others followed suit. Complaints were even sent when the destructor was not in use. For instance, on one occasion new iron bars had to be put in the furnaces and for this purpose the fire had to be put out for a whole week. In spite of this complaints were made as usual. The fact is, that bad odours may arise from other causes. It was further pointed out to me that close to the destructor there are two tripe-boilers, a slaughter-house, and an iron-foundry with a blasting furnace that has not got a proper chimney. Then there are also four lime-kilns in the neighbourhood. But there are now a certain number of people whose minds are so impregnated with the destructor grievance that any odour which they may notice is at once put down to that one cause.

The complaints received by the town council did not flow in regularly. Sometimes they stopped altogether and this for as long as three months at a time. It cannot be said that the wind blows the fumes away from the town for so long a period. The worst time was undoubtedly during the summer. The refuse was then very light and there was not enough to keep the furnaces burning actively for the whole of the 24 hours. Therefore, from about midnight to eight o'clock on the next morning the destructor had to cease working. This intermittence caused the nuisance, for the combustion was imperfect while the temperature was being raised at the resumption of work. Also, it must be borne in mind that coals cost from 28*s.* to 30*s.* a ton at Torquay and therefore they are carefully economised. Every household has a cinder-sifter and there is consequently very little unburnt fuel in the ashes. In November, 1900, the boundaries of Torquay were extended to include the Marychurch and Chelston urban districts. This increased the population by 12,000 and consequently there is now enough refuse to keep the destructor going all night. But on Saturdays the work ceases at two o'clock P.M. and is not resumed till Monday mornings. The difficulty of raising the temperature which occurred every day has now only to be met on Monday mornings. Apart from this, if the attendants neglect the cells or allow them to get choked up and fail to extract the clinkers this may cause an unpleasant smell ; and such carelessness happens more frequently at night time. As the greater number of complaints relate to odours occurring at night this shows that the complaints are not all imaginary, since so many of them mention the very time when it is recognised that a nuisance may be caused by mismanagement.

In regard to the nature of the refuse burnt it should not give rise to any special danger. The offal from the fish is not taken to the destructor ; the greater part is used by the fishermen as bait for their lobster pots, and what little remains is buried with lime. Indeed, it is claimed that the refuse is exceptionally clean. According to the investigations made for the town council 12 per cent. of the refuse consists of paper and cardboard packing, 52 per cent. of garden and vegetable matter, 6·5 per cent. of screened cinders, 25·5 per cent. of fine ash and dust, and 3 per cent. of broken pots, pans, bottles, crockery—in fact, of "hard core." There is only 0·3596 per cent. of rags and bones, and the rest consists of bits of bricks, old iron, coal, coke, and the like. Garden prunings constitute the principal distinctive feature of the Torquay refuse. Consequently those who argue in favour of the destructor urge that there is nothing especially dangerous or offensive in such refuse and it is maintained that when a genuine nuisance is created it is not of long duration and is only due to the inefficient management of the furnaces or to the temporary interruption of the operations. When the furnaces have to be relighted then faggots and steam coal have to be employed, and this gives rise to the black smoke that has been complained about on several occasions. Yet the employment of this fuel must be continued till enough steam has been generated to move the engines that drive the fan for the forced draught. This inconvenience can now be considered as in a great measure set aside, for since the extension of the borough boundaries there is refuse enough to keep the furnaces going during six out of the seven days. In regard to inefficient clinkering this also, it is promised, will be more carefully superintended. Finally, it is pointed out that the nuisance cannot be very serious or there would not be such a rapid

(FROM OUR OWN CORRESPONDENTS.)

### *Legal Fees of Expert Medical Witnesses in Ireland.*

IT will be remembered that an important decision in reference to the fees of medical men as witnesses in legal actions in Ireland was noted in THE LANCET some months ago. It was contained in the judgment of Mr. Justice Kenny, with whom Mr. Justice Barton and Mr. Justice Wright concurred, and it was to the effect that the fees for professional witnesses residing within five miles of Dublin were fixed by the schedule at one guinea a day for attendance in court unless in the opinion of the taxing master the case was exceptional and that, moreover, there was nothing exceptional in the particular case—an action against the Great Northern Railway Company of Ireland for damages for personal injuries in which the plaintiff was awarded £450. Mr. Justice Kenny held the opinion that the court was bound by the schedule and by the decision of the Master of the Rolls in Maconchy *v.* the Bank of New Zealand. He said that the taxing master was bound by the schedule not to allow more than one guinea a day to the medical men of Dublin, even to those of exceptional eminence The fees were accordingly reduced to the schedule allowance and the plaintiff gave notice of appeal. On Jan. 13th the case came before the Court of Appeal—Lord Justice Fitzgibbon, Lord Justice Walker, and Lord Justice Holmes. The most eminent members of the Irish bar were engaged. In the course of the argument it was stated that the taxing master had until quite recently made use of what was supposed to be his legal discretional power and, in fact, had allowed five guineas a day to medical men of eminence in Dublin for their attendance in court. He was examined and he is reported to have said that the case was in his opinion exceptional, because it had lasted for three days and had been adjourned over one day. Lord Justice Fitzgibbon, in giving judgment, said that on the questions put to the taxing master and the answers given they were not justified in making this an exceptional case or to increase the allowance under the scale. It was, he said, almost impossible to lay down a hard-and-fast rule as to what was an exceptional case, but he was clearly of opinion that there were no exceptional circumstances in this case, and that the taxing master should not have exceeded the scale in his allowance. Lord Justice Walker with Lord Justice Holmes concurred, and the appeal was accordingly dismissed. The effect of this decision, by which the discretionary powers of the taxing master in Ireland as regards legal fees to medical witnesses are so circumscribed, is of much importance. It is difficult to see in what direction it may trend. Medical men of position in Dublin will certainly refuse to help the courts of law and to give evidence under the reduced schedule of legal fees Their fees must therefore in future be guaranteed to them beforehand by the litigant who requests them to give evidence That, *primâ facie*, seems objectionable. It seems unfortunate that the law in England as regards many small but important matters fails to stretch over to us.

### *Royal College of Science for Ireland.*

Early last year a committee appointed by the Government recommended that the buildings in St. Stephen's-green, known as the Royal College of Science for Ireland, should cease to be used for science, and that the present Science and Art Museum, with a frontage in Kildare-street and another in Merrion-square, should be extended in order to embrace the work of the Royal College of Science and also that of the new and important Department of Agriculture For that object the Government has now determined to buy almost the whole west side of Upper Merrion-street, which is virtually an extension of Merrion-square West. It has been definitely decided to purchase the 13 mansions and houses extending up Merrion-street from the Government Museum Department in Merrion-square. The frontage is over 100 yards, and as the houses, gardens, and stables in Upper Merrion-street extend back for nearly 100 yards (288 feet) the Board of Works will thus acquire an area of about 100 yards square in the very best part of Dublin. The local papers have not noticed the matter and are probably unaware of its importance. From the medical point of view it is not devoid of interest, for Upper Merrion-street is only second to Merrion-square North as a favourite habitat for the medical profession of Dublin. They are almost all owners of long leases of the houses which they occupy. They have recently received notice from the Board of Works that application is intended to be made to Parliament in the ensuing session for an Act to acquire by compulsory purchase or otherwise the lands, houses, buildings, and premises in Merrion-street. The medical men who live along the northern side of Upper Merrion-street must therefore soon look out for houses elsewhere.

### *Coleraine Cottage Hospital.*

At the annual meeting of the subscribers held in the town hall, Coleraine, on Jan. 15th, it was reported that 71 cases had been treated during the year, and that 27 operations had been performed, all of which had been successful. The ordinary expenditure for the year was £444 3*s.*, and the ordinary income £444 2*s.* 10*d.*, of which the patients paid £105 2*s.* 6*d.* The other sources of income were chiefly subscriptions, donations, and church collections.

### *The Fund for the Family of the late Mr. W. Smyth.*

At a meeting of the Belfast committee of this fund held on Jan. 17th the report of the audited accounts showed that the Belfast subscriptions were (after paying the necessary expenses) £1328 6*s.* 11*d.* Since this audit further subscriptions of £21 19*s.* have been received and the Belfast Banking Company are kindly allowing interest on current balances. As the result of letters to the London press by "A Hospital Nurse" nearly £600 have been collected by Mrs. Henry Arthur Jones, of Portland-place, London, and this amount is to be amalgamated with the Belfast fund, making nearly £2000 in all. It is understood that the total of the combined fund raised for the family of the late Mr. Smyth will be £6000 The money is to be invested in a board of trustees as follows: the Duke of Abercorn, Mr. John Herdman, D.L., Mr. H. T. A. Warnock (Donegal), and the President of the Royal College of Surgeons in Ireland. Special votes of thanks were passed to the press, to Dr. W. H. Allen (Stanmore, Middlesex), to Miss Russell Geddis (the "Hospital Nurse" who originally wrote the letters to the *Standard*), to Mrs. H. A. Jones, and to all who had so kindly assisted the fund by collecting.

### *Lamentable Disaster in Belfast.*

Belfast was on Jan. 20th plunged into the deepest sorrow and mourning by a terrible accident which occurred in one of the large flax-spinning and weaving mills. About 9.30 in the morning a portion of the outer wall on the east side of the building gave way (due probably to a fracture of one of the cast-iron beams which rest on the brick piers through what is known as crystallisation in the iron), with the result that the heavy machinery was precipitated through the five storeys of the mill to the basement, carrying down many unfortunate workers and burying several under the débris. As a result of this most awful calamity—the most terrible which has ever occurred in the industrial history of Belfast—13 people have been killed and 12 patients—some very seriously injured—are lying at the Royal Victoria Hospital, Belfast. A rescue party, consisting of mill-workers, firemen, police, members of the salvage corps, and medical men, set to work to remove the débris, which consisted of several hundred tons of broken bricks, cement, and stonework, intermingled with iron beams and twisted and damaged pieces of machinery. A terrible scene was presented to the onlooker, while the noise was appalling owing to the cries of the terrified workers who had escaped, mingled with the groans and shrieks of those who had been partially engulfed. The task of clearing the fallen material was almost superhuman, the difficulty being due to the huge masses of heavy iron and steel machinery, but as the result of continued effort throughout the whole day and night, relays of workers being employed often at great personal risk, the work was accomplished, and one by one the unfortunate victims were rescued and conveyed in the fire brigade ambulances (of which three were constantly employed) to the Royal Victoria Hospital, where the most perfect and ample arrangements were made for their reception and treatment. The great feature of the cases, from a medical point of view, was the extreme shock. Simple and compound fractures of the limbs, severe head and pelvic injuries, and cases of damage to internal organs were among those admitted. The newspapers all speak in terms of the very highest praise of the splendid work of the rescue party, of the ambulance arrangements, of the devotion of the medical men who gave their services at the scene of the disaster, and of the thorough attention and care given to the unfortunate sufferers at the Royal Victoria Hospital.

Jan. 21st.

the time limit to enable the committee to raise the balance. In the meantime the committee has acquired a most suitable property at Maghull, which contains, in addition to a farmhouse and land, a modern residence which will be utilised as an additional home for female patients. There are now 70 male and 67 female patients in the three buildings of the "home," and many applicants are awaiting admission.

### *Liverpool Country Hospital for Chronic Diseases of Children.*

The treasurer of the above-mentioned institution reports that the efforts made for the collection of subscriptions towards the erection of the new hospital have been greatly encouraged by the generosity of friends, £8333 having been promised in addition to the amounts previously announced.

### *The Proposed Leigh Infirmary.*

The subscription list for the proposed Leigh Infirmary was opened last week and already over £8000 have been promised, including £2000 from the trustees of the Frances Charity, and £1000 each from the Leigh Coöperative Society, the Bedford Brewery, and the executors of the late Miss Farnworth. The Mayor of Leigh has subscribed £200. Lord Lilford has given three acres of land for building purposes.

### *The Liverpool Medical Institution.*

Mr. Rushton Parker has been elected the President of the Liverpool Medical Institution. Mr. Rushton Parker is the professor of surgery in University College, Liverpool, and is one of the honorary surgeons to the Liverpool Royal Infirmary. He is also an examiner in surgery at the Victoria University.

### *Scheme for a Psychiatric Clinique in connexion with the Edinburgh Royal Infirmary.*

A WEEK ago a circular letter was addressed by Sir John Sibbald, M.D., late Commissioner in Lunacy, to a number of the leading physicians in Edinburgh and to a few prominent laymen, asking them to meet him at the Royal College of Physicians of Edinburgh to consider a proposal to establish a ward in the Royal Infirmary for the treatment of mental disorder in its early stages. The meeting was held on Jan. 21st in the afternoon. The chair was taken by Professor T. R. Fraser, President of the College, and there was a strong and representative attendance of hospital physicians and of asylum superintendents. A lord of session and several members of the board of management of the infirmary were also present. Professor Fraser, in intimating the reasons for calling the meeting, dwelt upon the fact that there were many cases of early mental disorder which called for careful and skilful treatment, such as could only be suitably provided in wards like those that the originators of the movement had in view. Sir John Sibbald was then called upon and he read a statement of his views. He dwelt upon the absence of provision for the hospital treatment of early cases of mental disturbance—the stage at which it was impossible to certify the person as insane, and therefore inadmissible to an ordinary asylum. At this stage it was of the greatest importance to the patient that he should be under careful medical treatment, and often of equal importance that he should be removed from his ordinary domestic environment. Many patients might by this means be saved from becoming hopelessly insane and ending their days in an asylum. Another class that would be benefited would be the cases of acute insanity of a temporary nature which could be successfully treated in the special wards of a general hospital without the stigma which was attached to even a short residence in an asylum as a certified lunatic. He referred at length to the system in vogue in Germany. He also dwelt upon the subject from the standpoint of its importance to the student who was to be a practitioner. The study of certified lunatics had become compulsory, but he thought that it was still more important to teach the student to recognise the early manifestations of disordered brain function and how to adopt suitable measures for the arrest of the condition at this stage. He held that the best possible arrangement was to have special wards for the reception and treatment of these cases in a general hospital, and this in Edinburgh meant the Royal Infirmary. Such wards would form the basis of a psychiatric clinique in connexion with the medical school and would be of great advantage to the student. Sir John Sibbald evidently thought that nervous cases other than mental ones might also be included, but this part of his statement was wanting in clearness. He was followed by Dr. Macpherson, one of the Commissioners in Lunacy, who supported Sir John Sibbald's proposals. Dr. T. S. Clouston referred to the teaching of psychiatry in Edinburgh; how it had commenced at the Morningside Asylum, where the university instituted a lectureship in insanity and where now the course was compulsory. He entirely approved of hospital wards for the early cases and the establishment of a hospital clinique, and he suggested that an arrangement might be made between the infirmary and the county council whereby certain early and acute cases might in the first place pass through a special ward in the infirmary. After some further remarks a committee was appointed to consider the matter in detail.

### *The Morison Lectures.*

These lectures are delivered this year by Dr. G. A. Gibson in the Royal College of Physicians of Edinburgh. The subject chosen by the lecturer is "The Nervous Affections of the Heart." The first lecture was delivered on Jan. 20th, before a good audience. The part of the subject dealt with was "The Clinical Features of Sensory Disturbances." The three lectures of the present session he intended to devote to sensory affections. He dealt with the history of his subject, showing that the modern scientific aspect had its first formal presentation by Heberden in 1768, but that Edward Jenner and John Hunter had associated heart pain with changes in the nutrient arteries of the heart. He next proceeded to describe the general features of painful disorders of the heart, showing that the different symptoms were accompanied by objective phenomena, such as skin tenderness in the area of pain; and discussing alterations in the movements and sound of the heart, in the pulse, in the respiratory movements, and so forth. He then considered classification, condemning the division into true and false, but adhering to two groups, organic and inorganic. In the former were placed all the varieties depending upon obvious changes in the heart and great vessels within the chest, while in the latter were placed all those in which there were no definite structural changes, including toxic and neurotic.

### *Memorial to the late Professor Henry Alleyne Nicholson.*

A movement has been initiated with the view of commemorating the late Professor Nicholson by the erection of a bronze tablet in the museum at Marischal College. Professor J. Arthur Thomson, Zoological Department, Aberdeen University, and Mr. John E. Marr, F.R.S., lecturer in geology in Cambridge University, have undertaken the preliminary steps and are prepared to receive subscriptions from "those who were friends, colleagues, collaborateurs or old students. It has been suggested that the memorial should take the form of a simple bronze tablet with an appropriate freize, including, for instance, symbolic representation of some graptolites and tabulate corals. We are convinced that the fittest memorial of our friend should be simple and spontaneous, and we invite suggestions if you are disposed to assist in the commemoration." The proposal has already met with warm approval, and it is hoped that those who had the honour and the pleasure of being instructed by one who has shed such lustre on the University of Aberdeen will send in their subscriptions to either of the honorary secretaries as soon as possible. It has been suggested that should funds be sufficient a Nicholson prize in zoology might be instituted.

### *Aberdeen University "At Home."*

The Aberdeen University Association of Lecturers and Assistants gave an "At Home" at Marischal College on Jan. 18th. The guests numbered about 200

### *Aberdeen Students' Representative Council.*

At a meeting of the above council at Marischal College on Jan. 18th it was decided unanimously to give the sum of five guineas from the funds to the students' fund in connexion with the University extension scheme. This fund now amounts to £250 The council agreed to become patrons of the bazaar of the University Athletic Association to be held in October, 1902, for the purpose of aiding the funds of the association. Delegates to the Scottish Inter-University Conference in Glasgow were appointed.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Accident to Professor Virchow.*

PROFESSOR VIRCHOW, whose eightieth birthday was the occasion of great celebrations a few months ago, has unfortunately met with an accident which may possibly have serious consequences. While travelling in an electric tram-car he jumped off before the car had completely stopped and fell on the asphalte roadway. After being carried home he was attended by Professor Körte who discovered a fracture of the femur. This unfortunate occurrence has evoked great sympathy in every class of the population. The Emperor sent a representative to Professor Virchow's residence to inquire as to the condition of the distinguished patient, and many public bodies and associations—political and non-political—did likewise. The Berlin Medical Society when appointing officers for the current year at the first meeting in January unanimously re-elected Professor Virchow as president, and sent him a telegram of sympathy.

### *Dues payable to the Medical Chambers.*

A recent law requires the qualified medical men of a district to pay every year to the treasurer of the medical chamber of the district a sum proportionate to their incomes. The money is used for the expenses of the chamber and for a fund to support distressed members of the profession. At the last meeting of the Berlin Medical Chamber a petition was read on behalf of a certain number of professors, *privat-docents*, assistants, &c., who although duly qualified are not engaged in medical practice and some of whom have never practised. These medical men hold appointments in the physiological, pathological, anatomical, and other scientific departments of the university, or in the municipal hospitals. They pointed out that being exclusively occupied with scientific questions they were not in the least concerned with the topics bearing on the interests of medical practice which were exclusively discussed and decided in the Medical Chamber; their position differed entirely from that of the medical practitioner, and the medical chamber had never given any attention to their special interests. In the discussion which ensued Professor von Bergmann said that the petition was altogether ill-advised; that theoretical medicine must always have a connexion with medical practice, and that the representatives of the former should never forget that they had a good deal to do with practical medicine as members of examining boards and in other capacities. The petition was unanimously rejected; it was then stated that the petitioners had always paid their contributions to the medical chambers without any objection, and that they had even used their right to vote at the elections for the chamber. At the same meeting the chamber agreed to a motion that it was desirable when plague was prevalent in a district to cremate the bodies of the deceased instead of burying them.

Jan. 20th.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

### *Mental Soundness of Eddyites.*

THE Surrogate's Court of New York County holds in *re* Brush's will that, however the teachings of "Christian Science" may be opposed to the beliefs and notions of many, being founded on the religious conviction of those professing them, the court cannot say that those persons holding them are mentally unsound, as the truth or falsity of a religious belief is beyond the scope of judicial inquiry. The court also says that it has often been urged to pass an opinion upon the falsity of spiritualism and to hold that a follower of that faith, like Eddyism, as holding beliefs contrary to those of most men, was of necessity labouring under an insane delusion, but that it has uniformly refused to declare or to hold this opinion. The question for the court to decide in determining the testamentary capacity of a "Christian Scientist" is as to the effect of the belief upon his or her mind, the belief itself not being an evidence of insanity. The question which arises is whether this belief has displaced judgment, dethroned reason, and so made the person incapable of making a will. If the effect of this belief has been to fill the mind with insane delusions resulting in the testator's will then the document must certainly be set aside. In the case before the court it was decided that the testator was of sound mind.

### *The Liability of Physicians in Local-Option Territory.*

The Court of Criminal Appeals of Texas says in McLain *v.* the State that the legislature, as it holds that it had a right to do, has decided that for medicinal purposes intoxicants can only be sold upon a prescription certifying that a regular physician signing the prescription has personally examined the party to whom the prescription is given and that he is actually sick, and that that physician must testify to this upon his honour. These are the requisitions of the legislature. There is no kind of prescription authorising the sale except that provided by the statute, and even that is no prescription until the law has been complied with. In the event of a sale an illegal prescription is no protection to the seller or to the physician, because in that case the latter makes himself a party to the sale by giving an illegal prescription by means of which the law is evaded. As in misdemeanours all are principals, so an illegal prescription given by a physician involves him equally with the seller; both are liable, for each is required to know the law; and to bring about the sale each is obliged to comply with the requirements of the law, and failing in this one is as liable as the other for the punishment ordered for illegal sales. The court further states that it is not now dealing with a physician who gives a false certificate though in the exact terms of the law. In this particular case the court holds that a prescription was properly excluded because it was not in conformity with law, as it had omitted the expression "personally examined" and the certificate upon honour required by the statute.

### *A Year's Immigration.*

The annual report of Commissioner Powderly of the Immigration Bureau shows the total steerage arrivals in the United States in the year to have been 487,918, an increase over the preceding year of 39,346, or approximately 9 per cent Of this increase 2020 came from Canadian ports and the remainder through United States ports. There were also 74,950 other alien passengers who came as cabin passengers, making a total for the year of 562,868. The ratio of increase of Italian immigrants as compared with that of last year from that country is approximately 36 per cent., or more than threefold the ratio of increase from all Europe, and the increase numerically from all other countries of Europe aggregates scarcely one-fourth of that from Italy. The total steerage immigration was distributed as to sex between 331,055 males and 156,863 females, and as to age between 62,562 under 14 years, 396,516 from 14 to 45 years, and 28,840 over 45 years. It is shown that 117,587 were unable to read or write, 3058 could read but not write, and that 294,860 brought each less than $30, and 56,312 had more than $30 each. During the past year 363 persons have been returned to their respective countries, having become public charges within one year after landing. The number not allowed to land was 3516, against 4246 last year. The report shows that the character of the immigrants was decidedly superior to that of last year, the rejections being 730 less though the arrivals were 39,346 more. The principal countries from which the steerage arrivals come are as follows: Italy, Sicily, and Sardinia, 135,996; Austria-Hungary, 113,390; the Russian Empire and Finland, 85,275; Ireland, 30,651; Sweden, 23,331; the German Empire, 21,561; Norway, 12,248; and England, 12,414 In discussing the general subject of immigration the Commissioner-General says that to deal with the problem successfully it seems indispensable to remove as far as possible those conditions which conflict with the incorporation of the alien element into the social system of America, in order that by actual experience the former may learn as soon as possible that the basis and foundation of the American polity are a respect and affection for, and a willing obedience to, the laws and customs of the land, because the maintenance of these laws is the best safeguard of personal liberty. It is therefore recommended that Congress should enact suitable legislation, either with, or if necessary without, the coöperation of the States, for the purpose of distributing the alien population with some reference to the industrial law of supply and demand.

### *Ship Surgeons and Shipping Companies.*

A SPECIAL diploma for ship surgeons (*diplôme de médecins sanitaires maritimes*) was introduced some years ago. Provided with this qualification a medical man could fulfil the duties of surgeon on board a merchant vessel or transport, but the new diploma left him in the position of a mere servant of the shipping companies, although his duties included the carrying out of sanitary measures. It has often been suggested that ship surgeons should have the status of Government officials, but no steps have been taken in this direction, and men whose duty it is to act in the interest of public health remain the paid servants of employers upon the adequacy of whose arrangements they may have to express an opinion. Under these conditions disputes were inevitable The ship surgeons founded a society and believed that in it they had a right to discuss questions of hygiene and to criticise the measures adopted by the companies for the prevention of disease. These measures are not so good as they might be, the fact being that the shipping companies, although in receipt of considerable bonuses from the Government, trouble themselves very little about the welfare of their passengers, as has been recently shown in the case of the *Senegal.* The criticisms uttered in the society of ship surgeons gave offence and the president of the society has been discharged by the company in whose service he was. Painful examples are not wanting of the scanty consideration entertained by the shipping companies for the surgeons on board their vessels A surgeon became seriously ill while passing through the Red Sea and arrived at Marseilles in a delirious condition. The company who employed him set him on shore, refusing to have anything more to do with him, and the police commissary of the Quartier de la Jolette had to order an ambulance and to procure his admission into one of the general wards of the Hôpital de la Conception. Under these circumstances the only advice that can be given to the ship surgeons is that they should form an association and should bring the shipping companies to understand, even by means of a strike if necessary, that they are entitled to better treatment.

### *Diphtheria in Paris.*

Diphtheria being increasingly prevalent in Paris, the Municipal Health Committee at its last meeting discussed the sick- and death-rates occasioned by this disease in Paris last year. The committee recommended that copies of the official instructions relative to diphtheria should be sent to the families who have children absent from school from this cause; that these instructions should also be sent to the medical men of the districts in question; that local health committees and medical societies should be asked to discuss the prophylaxis of diphtheria at their meetings; that the committee on insanitary dwellings should be informed of the addresses at which cases occur; and that public and private schools should be medically inspected.

### *Infant Feeding and Infant Mortality.*

The Academy of Medicine, on Jan. 14th, acquiesced in the conclusions presented to it in a report made by M. Porak at the instance of the Committee upon the Hygiene of Infancy. The conclusions were brief and succinct. The milk of the mother, or, failing the mother of some other nursing woman, is the best method of feeding the infant. If human milk cannot be obtained, animal milk—cow's, goat's, or ass's milk—ought to be given. Feeding-bottles with tubes ought to be interdicted by law, as being responsible for great infant mortality M. Porak refers to a report of the Academy stating that only children nursed *à domicile* are submitted to the legal inspection provided under the Roussel Act, and proposes to open an inquiry into the working of this Act which he considers unsatisfactory and partial The Academy has decided that the control of home-nursing ought to be more thorough. As the possible causes of death to the infant are most numerous during the first month of life the Academy recommends that the visits of the *médecin inspecteur* should be weekly during that period, fortnightly for the next four months, and monthly during the sixth and seventh months. Lastly, to obviate one of the reasons, trifling in appearance but really of the first importance, preventing nursing women from applying whenever necessary to the *médecin inspecteur,* the Academy suggests that such women should be admitted to the benefits of the Assistance Médicale, and that foster-mothers should have legal help in any process against the parents for the recovery of their wages.

### *Parasites in the Blood of Epileptic Patients.*

M. Bra has taken specimens of blood from the veins of the forearms of 70 epileptic patients under the care of M. Magnan in the Hospital of St. Anne, and also under the care of M. Marandon de Montyel at the Asylum of Ville-Evrard. All these patients were suffering from the form of epilepsy which is called idiopathic, and M. Bra has been able at certain periods of the affection to demonstrate the unvarying presence of a micro-organism. During the lengthened period which intervened between the paroxysms, examination very often gave a negative result, but when the blood was examined just before the attack, or during or immediately after an epileptic crisis, small, feebly refracting points could be seen in the plasma. They were 1μ and under in length, and were seen either alone or as diplococci. They moved very rapidly sometimes, either singly or united together in greater or less numbers, and while thus united they presented the appearance of little worms of a length equal or superior to the diameter of a red blood corpuscle. Generally, six or eight of these bodies were seen together. They presented various forms, but the most typical was that of a chain terminated at each extremity by a larger body somewhat resembling a chain-shot. They moved about with serpentine movements and tumbled the one over the other. Very often they became rolled up into balls, so that it was impossible to be certain of their real form, and sometimes they were seen adhering by one extremity to a red blood corpuscle. Apparently they are some form of streptococcus which, owing to its morphological and biological characters, constitutes a very special variety, and one which M. Bra has never found except in epileptics.

### *The Consumption of Various Drugs by the Paris Hospitals.*

*Médecine Moderne* has got together some remarkable extracts from a report presented to the Municipal Council by M. Houdé upon the Central Hospital Dispensary. Here are some of the figures for 1901: The total expenses were 1,981,820 francs, of which 142,420 francs went for general expenses, being an increase of nearly 500,000 francs over the figures for 1890. Passing on to expenses for drugs properly so-called, in 1899 61,000 francs were expended in drugs, as against 34,000 in 1890, and another 80,000 francs for vegetable drugs (*herboristerie*), as against 44,000 francs in 1890. Various chemicals cost 321,000 francs, as against 220,000 francs. The quantity of coffee remains almost the same, that is to say, 39,000 francs as against 38,000 francs, but the consumption of sugar has gone up very remarkably—viz., 216,000 francs, as against 157,000 in 1890 Leeches are a small item. There were only 250 francs worth used in 1899 and 224 in 1890. The consumption of glycerine has, however, increased very much, the figures being 79,000 francs, as against 43,000. 63,000 kilogrammes were used at the various hospitals, and of this total the Lariboisière Hospital alone used 7621 kilogrammes, or as much as the Hôtel Dieu and the St. Louis Hospital together. It is a remarkable thing that no enemata are given at this hospital, but it seems to be particularly profuse in the use of medicines. The total consumption of iodine at the various hospitals was 11 kilogrammes, and of this quantity the Lariboisière Hospital used 60 per cent., and out of a total quantity of 5625 grammes of tincture of musk 3060 grammes, or 54 per cent., were used by the Lariboisière Hospital. The report is in utter despair about the consumption of alcohol. In 1890 pure alcohol cost 86,000 francs. In 1899 the expenses had gone up to 219,723 francs. As regards rum, the expense is almost doubled, and again the Lariboisière Hospital comes out at the top. The total quantity of rum for the various hospitals amounted to 35,527 litres, and of this quantity the Lariboisière Hospital took 6428 litres. As a rule, the rum is used up in making "Todd's drink" and "*thé au rhum.*" The report considers that 36,000 litres of camphorated alcohol, which has apparently been used, has not been employed in a proper manner. This preparation, it appears, is not only used in the hospitals to rub patients with, but it is used very extensively for cleaning windows. Camphorated alcohol appears to be an admirable thing to add to whitening. When windows are cleaned with this mixture the alcohol evaporates and the camphor which is left behind seems to have a wonderful effect in making the glass highly polished and bright.

Jan. 21st.

fan. The meat would in this way be protected completely from contamination by the hundred-and-one forms of filth which are blown about in every large town, while the appeal to the customer's eye would still be as strong as it is now, and far more pleasing would be his reflections." Dr. Mason also indicts the system under which milk is supplied to the consumer. He says: "There is, unfortunately, not the slightest room for questioning the truth of many of the statements which have been made in reference to dirty milk. It cannot be otherwise when one considers the slipshod methods in use by the retailer as well as by the buyer of the milk. It would be unfair to a great number of milk-vendors to say that all are dirty, but the fact remains that not a few of them take little or no trouble to profess the virtue of cleanliness, even if they have it. The cans are not bright, the carts are often dirty, and the clothing of the dispenser not infrequently shows unmistakeable evidence of a rubbing acquaintance with cows and cow-bails. Then again the customer aids and abets the vendor by providing an open vessel like a jug to receive the dust and dirt as well as the milk. It seems marvellous that no company has seen its way to undertake the retailing of milk in the tasteful, cleanly way in which one sees it done on the continent and in some parts of London—bright clean carts, clean polished pans, Pasteurised milk from guaranteed herds, and, above all, clean, tidy servants, dressed in spotless linen—and success, I feel sure, would be attained." The report deals exhaustively with the question of phthisis, and concludes with a reference to the educative work in sanitary matters carried on by Dr. Pomare, native health officer, among the Maori population.

Dec. 18th, 1901.

## Obituary.

### WILLIAM NASH, M.D. EDIN., M.R.C.S. ENG.,

SURGEON-GENERAL, A.M.S. (RETIRED).

ON the early morning of Jan. 19th Surgeon-General W. Nash unfortunately succumbed to pneumonia (the result of a chill caught during the previous week) to the deep sorrow of his numerous friends, and these will include all who have ever had the honour of his acquaintance, for no officer possessed in a greater degree the innate quality of attracting the affection of his equals and subordinates. He was educated at King's College Hospital and at Edinburgh University, and on entering the army was in the 72nd Seaforth Highlanders. He served for 38 years in the medical service of the army. His war services included the Kurram campaign under Lord, then Sir Frederick, Roberts, where he was present at the battle of the Peiwar and the occupation of the Shuturgurdan (despatches, medal, and clasp), and the Egyptian campaign under Viscount Wolseley (medal and bronze star). His last office was that of principal medical officer of Netley, during which time he twice had the honour of receiving her late Majesty at the hospital. During his whole career Surgeon-General Nash's qualities were such as to make him beloved by all officers and men who came into contact with him. Ever ready to help any brother officers, he yet knew how to exercise firm discipline when necessary.

### WILLIAM SMITH LUNAN, M.B., C.M. ABERD.

INTIMATION was received early this week of the death, on Dec. 27th last, of Dr. William Smith Lunan, son of Mr. William Lunan, C.A., Aberdeen Deceased was a native of Aberdeen and studied at Marischal College, where he graduated M.B., C.M. He then proceeded to Fort Beaufort, South Africa, and entered into partnership there with Dr. Pearson. He subsequently acted as a surgeon in the Matabele War and was surgeon-captain in the British South African Police. About a year ago he transferred his services to the Globe and Phœnix Mine, Rhodesia, which post he occupied at the time of his death. Dr. Lunan was about 40 years of age. He married Miss Quin whose father was a member of the Cape Parliament. His family numbers four. In Aberdeen the news of his death has been received with much regret.

### WALTER LAWRANCE, M.R.C.S. ENG.,

FLEET SURGEON, R.N.

A WIDE circle of friends will hear with deep regret the news of the death of Fleet-Surgeon Walter Lawrance, R.N. (retired), which took place on Saturday, Jan. 18th, at his residence, 5, East Craibstone-street, Aberdeen. A native of Aberdeen, Fleet-Surgeon Lawrance was educated at the Grammar School and Marischal College. He entered the Royal Navy in October, 1841, and was made surgeon in 1852. Two years later he was promoted staff-surgeon and subsequently attained the rank of Fleet-surgeon. For a considerable period he was stationed on the West coast of Africa and also at New Zealand. The last three or four years of his service were spent on H.M.S. *Clyde*, but he retired nearly 30 years ago. Fleet-Surgeon Lawrance took no part in public affairs. In private life he was one of the most genial and kind-hearted of men. He is survived by a widow.

## Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In January the following candidates passed in the subjects indicated:—

*Surgery*—J. W. W. Adamson (Section II.), St. George's Hospital; A. G. H. Anthonisz (Section II.), University College Hospital, A. H. Bell, Cork and Guy's Hospital; H. E. Darlington, Birmingham; A. Dewar, McGill and Westminster Hospital; and F. M. Payne (Section II.), Royal Free Hospital.

*Medicine.*—J. W. W. Adamson (Section II.), St. George's Hospital; A. A. E. Baptist, Calcutta; F. G. Bennett (Section I.), Cambridge and University College Hospital; E. C. Curtis, Aberdeen and Charing-cross Hospital; C. J. Francis, Guy's Hospital; J. Hunter (Sections I. and II.), McGill and Westminster Hospital; W. Miles, Middlesex Hospital; R. Rees (Sections I. and II.), Cambridge and St. Mary's Hospital; and H. Salomon, Manchester.

*Forensic Medicine.*—J. Hunter, McGill and Westminster Hospital; T. G. Miles, Guy's Hospital; R. Rees, Cambridge and St. Mary's Hospital; G. Roper, Cambridge; and H. Salomon, Manchester.

*Midwifery.*—J. J. Anning, Leeds; F. G. H. Cooke, University College Hospital; F. I. M. Jupe, Cambridge; F. H. Maberly, Birmingham; and E J. Miller, King's College Hospital.

The qualifying diploma of the Society in medicine, surgery, and midwifery was granted to the following candidates: J. W. W. Adamson, A. G. H. Anthonisz, A. A. E. Baptist, A. Dewar, C. J. Francis, F. M. Payne, and R. Rees.

UNIVERSITY OF CAMBRIDGE.—The following degrees in medicine and surgery were conferred on Jan. 16th:—

*Bachelor of Medicine.*—J. W. Rob, St. John's; K. R. Hay, Caius; and E. G. Wales, Downing.

*Bachelor of Surgery.*—A. G. Bate and E. I. Claxton, King's; A. H. Greg, Trinity; J. W. Rob and J. Wharton, St. John's; R Rolfe, Clare; H. M. Wilson, Trinity Hall; C. de Lisle Carey, Emmanuel; E. G. Wales and T. E. Wood, Downing; and F. H. M. A. Beckett, Selwyn.

Dr. Barclay-Smith has been appointed Senior Demonstrator of Anatomy for a further period of five years. An additional examination for Part I. of the Third M.B. will be held early in June under the new regulations to suit the convenience of students who desire to proceed to their work for the final examination.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Gustav de Ruyter, *privat-docent* of Surgery and joint author with Dr. E. Kirchhoff of a surgical compendium, has been granted the title of Professor, as have also the following distinguished medical men who are not connected with the teaching staff of the University: Dr. Theodor Sommerfeld, a Berlin physician who has written a good deal on the subject of tuberculosis; Dr. George Meyer, who has made a special study of sanitary and ambulance organisation in England and elsewhere; and Dr. Julius Schwalbe, one of the editors of the *Deutsche Medicinische Wochenschrift*.—*Bonn:* Dr. Karl Hubert Vogel, one of the surgeons of the Johannes Hospital, has been recognised as *privat-docent* of Surgery.—Dr. Bleibtreu, Assistant in the Physiological Institute, has been granted the title of Professor.—*Breslau:* Dr. E. Storch has been recognised as *privat-docent* of Psychiatry.—*Copenhagen:* Dr. F. C. C. Hansen has been appointed to the chair of Anatomy in place of the late Professor Chievitz.—*Erlangen:* Dr. Max von Kryger has been promoted to be extraordinary professor of Surgery.—*Königsberg:* Dr. Heinrich Jäger, *privat-docent* of Hygiene, who has made some valuable bacteriological researches, has been granted the title of professor.—*Rio de Janeiro:* Dr. Miguel Conro has been promoted to the professorship of Medical Diagnosis.

VACCINATION GRANT.—Mr. S. H. Rentzsch, Week St. Mary, Cornwall, has received the Government grant for the second time in succession for successful vaccination.

appeal from the ruling of the Marine Hospital Service published last spring which placed tuberculosis among the infectious and loathsome diseases which are barred out from admission into the United States under the existing immigration laws. A circular letter was recently sent to the immigration commissioners at all the American ports for special reports as to the number of aliens affected with consumption who had arrived since July. An examination of the official replies revealed to the authorities that less than 50 immigrants had been debarred from admission on account of tuberculosis. At the port of New York only 34 cases had been reported, at Baltimore two, and at Philadelphia three. Of these latter one young woman died before she could be deported. *It is* understood that the assistant-secretary has come to the conclusion that the number of immigrants coming to this country with tuberculosis is not sufficient to require other than the exercise of the powers of the city board of health to guard against its spread and to care for the afflicted. He argues that if other nations desired to adopt retaliatory methods, with regard to which there has been some discussion, the United States would be a great sufferer.

### *Dinner to Dr. T. Gaillard Thomas.*

A banquet was given recently to Dr. T. Gaillard Thomas by his medical brethren, the occasion being the anniversary of his seventieth birthday. The dinner in his honour took place at Sherry's Restaurant, and was attended by nearly 300 members of the New York medical profession with the addition of a few from other cities. Dr. James W. McLane of the College of Physicians and Surgeons presided. Among the speakers were Dr. Weir Mitchell of Philadelphia, Judge Howland, Dr. William Welch of Johns Hopkins University, and Dr. Shattuck of Boston. A eulogistic sketch of Dr. Thomas's career was given by the President of the New York College of Physicians and Surgeons at which school Dr. Thomas had passed a portion of his life as a teacher of medicine. Dr. Thomas himself, who is known as one of the best orators in the American medical profession, made a speech which well upheld his reputation. Dr. Thomas is a native of South Carolina; he studied first at Bellevue Hospital School, after which he took courses in midwifery at the Rotunda Hospital, Dublin, and then spent some time in Paris, finally settling in New York. From 1855 to 1860 he was a lecturer on obstetrics at New York University, but after the Civil War the College of Physicians and Surgeons prevailed upon him to join its teaching faculty. Dr. Thomas's specialty has been the diseases of women, in which he has made himself a world-wide fame; he is the author of a standard treatise on that subject.

### *Tetanus in St. Louis.*

A commission which was appointed to investigate the tetanus poisoning in St. Louis subsequently to the use of antitoxin prepared by the Board of Health has reported that the diphtheria antitoxin so prepared was issued before it was possible to have obtained results from the usual necessary tests; and that had these tests been made the animal experiments would have proved the presence of tetanus germs and that the fatalities would have been avoided. The disastrous occurrences in St. Louis have given rise not unnaturally to a considerable amount of animus against the practice of boards of health manufacturing and distributing antitoxins. It is pointed out that antitoxic serums supplied by private manufacturers are prepared in almost all instances by trained bacteriologists who know the technique *necessary to protect* the serum from contamination, so that it is almost impossible that any serious impurities should gain an entrance into it. It would seem from the accident in St. Louis that marked carelessness prevailed both in the manufacture of the serum and in its distribution. The antitoxin which caused so many deaths in St. Louis was prepared at a municipal laboratory conducted upon an economical basis, not in a commercial laboratory run upon strictly business principles. In institutions of the former class politics are liable to enter and the help is rather likely to be chosen from among political favourites than from among those who are especially adapted for the work in question. The moral of the unfortunate events at St. Louis would seem to be that work of such scientific accuracy should be placed in the hands of those who can afford to engage the best possible assistance and who are able to choose their men entirely irrespectively of any outside influence or coercion.

Jan. 7th.

## NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

### *The Public Health Department.*

THE first report of the Public Health Department, which was presented to Parliament by the Minister of Public Health last month, naturally contains a good deal that is interesting generally, as well as much that is instructive. Dr. J. Mason—the chief health officer—prefaces his report with the statement that the Public Health Act of 1900 puts this colony in the van as regards the conservation of the public health. He indicates briefly what has been already done and the plans for the future. The colony has been apportioned into six divisions of much the same area and description as the old provincial districts. Each district will be under the charge of a district health officer, who must be a qualified medical practitioner and possess a special qualification in public health or sanitary science, or have special knowledge of sanitary and bacteriological work. He will be required, among other things, to inform himself as far as practicable respecting all influences affecting, or threatening to affect, injuriously the public health within the district; to inquire into and *to ascertain the causes, origin,* and distribution of diseases within the district and to ascertain to what extent they depend on conditions capable of removal or mitigation; to keep himself informed of the conditions injurious to health existing in the district; to be prepared to advise the various local bodies on all matters affecting the health of the district and on all sanitary points involved in the framing and subsequent working of such by-laws and regulations as they may have power to make; and to direct or superintend the work of inspectors of nuisances within his district. Under this system it is fairly expected that ere long many, if not all, of the conditions which militate against the health and well-being of the community *will be removed. The precautions adopted against the* occurrence of plague in the colony are outlined. Special regulations have been drawn up for the guidance of all who have to deal with cases of dangerous infectious diseases, providing for the isolation of persons, disinfection of persons and things, disposal of the dead, &c. "Our danger," Dr. Mason states, "lies not so much in the landing on our shores of a case of plague, but in the thousand-and-one insanitary conditions which exist all over the colony—conditions which make for the depreciation of the individual's power of resistance to disease, and at the same time form a happy hunting-ground for that most energetic of colonisers—the rat. Not from plague have we most to fear. Let but one case of small-pox escape the grasp of the inspecting officer, and within a few months there will be raised to that reaper who plies his sickle without note of season, a harvest before which the number of victims of plague would pale in insignificance. The responsibilities of the opponents of vaccination are great and 'conscientious objectors' are many, but it will be found if ever that scourge comes amongst us that assuredly the one will not be allowed to forget what he has sown though the other may disappear." Dr. Mason deplores the pollution of our rivers and streams by sewage and by refuse from factories and devotes some space to urging the importance of proper drainage of our towns. As regards the effect of the new drainage system in Wellington he says: "Previous to the completion of the present sewage system enteric fever used to occupy a not insignificant position both in the hospital records as well as the death-rate. At the present time, even although the house connexions are far from complete, this disease, which is one of the best barometers, so to speak, as to the sanitary condition of a community, has in a great measure disappeared." A phase of the meat-supply question is thus dealt with: "Were the retailers of any other article of diet to expose their wares in the way in which the butchers, large as well as small, do, there would be at once a great outcry. Take any of the best shops that we see in our large towns. The meat is exposed to every wind which blows, and to every particle of dust which is carried by that wind. *There is no question* whatever that disease can be carried and spread in that way. To remedy this should not be a difficult problem. The meat could be inclosed between two layers of glass, which space could be properly aerated by means of a

**New Isolation Hospital.**—At a meeting of the Stratton and Bude (Cornwall) District Councils held on Jan. 14th it was decided to erect an isolation hospital available for both districts.

**Vaccination at Exeter.**—At the meeting of the St. Thomas's (Exeter) Board of Guardians held on Jan. 17th it was decided to send out notices to the different parishes calling the attention of residents to vaccination and explaining that they could be vaccinated free of charge.

**Cottage Homes.**—A series of cottage homes has been built during the past year at Barnstaple on a site opposite to the main entrance to the workhouse, and on Jan. 17th the workhouse children went to reside in them. The homes are very neat buildings, the accommodation being admirable, and they are in charge of several foster mothers.—The Local Government Board has approved the plans for the erection, by the Bristol Board of Guardians, of cottage homes at Downend at an estimated cost of £16,920.

**West Cornwall Infirmary, Penzance.**—The annual meeting of the subscribers of this institution was held on Jan. 15th, under the presidency of Prebendary Hedgeland. The medical report stated that the in-patients numbered 135, and that 1710 out-patients were treated, showing in both instances a considerable increase as compared with 1900. The financial statement showed that the income amounted to £937, including £219 received from the Hospital Sunday Fund. The expenditure was £869.

**Valuable Collection of Antiquities.**—The valuable collection of antiquarian and natural history objects brought together by himself and the late Mr. Richard Walter, his father, has just been presented by Mr. Walter Winter Walter, M.R.C.S Eng., L S.A , of Stoke-under-Ham, Somerset, to the County Museum at Taunton. The collection, which has taken 60 years to accumulate, comprises, amongst other interesting objects, a unique series of pre-historic, Celtic, Roman, and Saxon remains from Ham Hill, Somerset, said to be the largest ancient encampment in the kingdom The collection, which will take some months to arrange, will occupy a room by itself in the museum and will bear the name of the donor. Lord Avebury has been invited formally to open the room.

**Donations and Bequests.**—By his will the late Mr. W. J. Ford of Edinburgh leaves to the Edinburgh Royal Infirmary £4000, to the Leith Hospital £4000, to the Royal Hospital for Sick Children £1000, and to the Queen Victoria Public Institute for Nurses, Scottish branch, £1000.—Lady Grimthorpe bequeathed £100 to King's College Hospital.—The Goldsmiths' Company has granted a sum of £50 to the Samaritan Free Hospital and £200 to the funds of the Metropolitan Convalescent Institution.—By the will of Miss Catherine Holgate, of South-parade, Burnley, who died recently, and also of the legacies which now become operative under the will of her sister who died in 1894, £400 are left to the Northern Counties Hospital for Incurables, £500 to the Burnley Victoria Hospital, and £200 each to St. Mary's Hospital and the Manchester and Salford Lying-in Hospital —A sum of £200 has been bequeathed under the will of the late Mr. A. Thorne, J.P., to the City of London Hospital for Diseases of the Chest, and the same amount to the National Hospital for Consumption at Ventnor and to the Royal Free Hospital respectively.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### *Prospective Legislation.*

The Session of Parliament was opened by His Majesty the King with a speech in which seven subjects of prospective legislation were mentioned. Only two of these subjects have any special interest for the medical profession, one the London water-supply and the other the amendment of the lunacy laws. It is probably safe to assume that the Bill dealing with the latter subject will follow the lines of the legislation proposed by the Government in former sessions. As for the London Water Bill its scope has been indicated by the title given to it by Mr. Long, the Minister who will take charge of it in the House of Commons, namely, "a Bill for establishing a Water Board to manage the supply of water within London and certain adjoining districts; for transferring to the Water Board the undertakings of the Metropolitan Water Companies; and for other purposes connected therewith."

### *The Midwives Question.*

The Bill "to secure the better training of midwives and to regulate their practice" comes before the House of Commons this session, backed by Lord Cecil Manners, Mr. Tatton Egerton, Mr. Schwann, Mr. Parker Smith, Sir John Batty Tuke, Sir Savile Crossley, Mr. Eugene Wason, Mr. Tennant, and Mr. Heywood Johnstone. These gentlemen were fortunate in the ballot and have secured for the second reading of the measure the first place on Wednesday, Feb. 26th. The only risk of the Bill not being discussed on that day is that the Government may appropriate the sitting for its own business. This is a somewhat remote contingency, and therefore it behoves critics and opponents of the measure to bestir themselves.

### *Medical Acts (Extension) Bill.*

General LAURIE has introduced again in the House of Commons his Bill bearing this title. Its general purpose is to extend the benefits of registration in this country to qualified medical practitioners in the colonies. The hon. and gallant Member was prompted to introduce the measure in the first instance by the refusal of the War Office to accept the services of Canadian rgeons for other troops in South Africa than those sent from t ominion. The Bill has never been discussed in the House and the spect of its being discussed during the present session is but slight.

### *The Pure Beer Bill.*

This measure, with which the name of Sir CUTHBERT QUILTER has been long identified, is once more before the House of Commons. Its promoters secured a good place in the ballot and the second reading of the Bill stands as the first order for Wednesday, April 23rd.

### *Cremation.*

Lord MONKSWELL has introduced into the House of Lords a Bill for the regulation of the burning of human remains and to enable burial authorities to establish crematoria.

## HOUSE OF COMMONS.

### FRIDAY, JAN. 17TH.

### *Preservatives and Colouring Matters in Food.*

Mr. CHANNING asked the President of the Local Government Board what steps he proposed to take in pursuance of the report of the Committee on Preservatives and Colouring Matters in Food.—Mr. LONG replied that he had not yet arrived at any decision with regard to this report; he was still considering it.

### *The Housing of the Working-classes.*

At this sitting of the House there was a long debate on the question of the housing of the working-classes. It was raised in connexion with the Address to the King in acknowledgment of the Speech from the Throne at the opening of the session. Dr. MACNAMARA moved an amendment to add these words to the Address—viz., "And we humbly represent to your Majesty that the greatest hardships are inflicted upon many of your working-class subjects by reason of the lack of proper housing accommodation, and that immediate Parliamentary attention to this evil is one of the most pressing of the necessities of domestic policy."—Mr. WALTER LONG, President of the Local Government Board, made the reply on behalf of the Government. He assured the House that this question was receiving the most serious attention of his department, and with regard to the case of the metropolis he reminded Members that already two large schemes under the Act of 1900 had been embarked on in London. He did not suggest that all the blame for what had been left undone rested with the local authorities, for he knew that in many cases they were striving with all their might to deal with this great problem; but some of them had been endeavouring to provide dwellings on land of such a value that it was impossible to let them at a rent within the reach of the people whom it was sought to benefit. In Hull admirable work had been done. There the local authority had cleared the slum area and had constructed a fine thoroughfare leading into the less populous parts of the town, and the private individual had come forward and put up suitable buildings on the property adjoining, the corporation doing the lighting, draining, and so forth. He ventured to think that that was the best solution of the problem where it was possible. On the subject of the proposed extension of the period for the repayment of loans Mr. Long announced that it was the intention of the Government to ask for the appointment this session of a committee of inquiry. He hoped that he would be able during the session to deal with the borough funds question, which did, no doubt, put difficulties in the way of some municipalities, and there were one or two other small matters which impeded local authorities in their usefulness, and which, he hoped, might be amended also this session. The House had been told that sometimes when a local authority put into force the powers it undoubtedly possessed and succeeded in closing an insanitary area it had to pay a great deal more for the land than it ought. There was insanitary property and insanitary property. In some cases a property became insanitary through the gross neglect of the owner, and clearly in such cases the owner ought to get no more than the actual value of the land. But a great deal of property became undesirable for habitation through no fault of the owner. There was often a confusion between these different classes of property; and he did not think that the majority of the House would ever consent to the confiscation of property solely because it was desired to make provision for the working-classes who wanted better houses. He had been engaged in the examination of this question, and he would look further into it: and he could assure the House that if he found, either with regard to the question of valuation or to any other part of the administration of the Act, that he required the assistance of a committee he would not hesitate to ask the House to consent to its appointment. He agreed with the suggestion that the whole of the administration of the Housing Acts should be in the hands of one central authority. A

**National Hospital for the Paralysed and Epileptic** —The following is the result of the poll for election to the board of management of the above hospital which was demanded at the meeting held on Jan 9th and was declared on Jan 23rd —

| A Royle | 191 | | |

**Newton Abbot Joint Isolation Hospital** —The committee of this hospital has decided to erect a corrugated iron hospital to contain 12 beds to be used, if required for small pox cases It will be placed in the grounds of the present hospital and will be worked from the main building The estimated cost is about £400 The Local Government Board refused to allow the present building to be used for small pox cases

**The Queen Victoria Jubilee Convalescent Home Durdham Down Bristol** —The sum of £4115 being the amount of the collections in Bristol on behalf of the ' Queen Victoria Memorial Fund has been handed to the committee of this convalescent home This will allow the governors to make free two additional beds and to reduce the charge for paying patients from 12s to 10s per week Quite recently Mr Vaughan has followed up his previous generous contributions by a donation of £10 000 which will be devoted to the endowment of 10 free beds This will permit 14 patients being admitted without payment The convalescent home is much appreciated locally, for during 1901 1017 patients were received in the institution

**Vaccination Expenditure** —At the meeting of the Warminster Board of Guardians held on Jan 13th it was reported that the fees for vaccination for the past quarter amounted to £165 which was an increase of £153 as compared with the corresponding quarter of 1900 A short time ago a few cases of small pox occurred at Warminster —At the meeting of the St Germans (Cornwall) Board of Guardians held on Jan 16th it was decided that no action should be taken as suggested by the Cardigan Board of Guardians in the reduction of vaccination fees one of the guardians remarking that several people considered the public vaccinators were not so well paid as formerly because they now had to make extra visits

**Society of Medical Phonographers** — This society will hold its next annual shorthand examination early in May Two prizes will be offered each of the value of £5 one for first year students and one for students of more than one year's standing The competition will be open without entrance fee to any registered medical student in the United Kingdom who has not taken a first prize at one of the society's previous examinations It will be held simultaneously in London Edinburgh Dublin and at any provincial medical centre in the United Kingdom at which not fewer than three candidates shall offer themselves Intending candidates should send in their names as early as possible to Dr P G Griffith Bonhams Farnborough Hants who will furnish them in return with a detailed prospectus of the examination The latest date for receiving entries will be April 15th

**Freemasonry** —The St Luke's Medical Lodge of Instruction held its first meeting on Monday Jan 20th at the Criterion Restaurant This Lodge of Instruction is the result of the work done by a committee representing the various medical lodges of the metropolis which was appointed last session to consider the subject Bro Ernest Clarke W M of the Æsculapius Lodge occupied the chair and was supported by Bro W Duncan and A. P Luff, of the Middlesex Hospital and Sancta Maria Lodges respectively and some 40 influential and representative members of the various medical lodges The principal business of the evening was the passing of the by laws at the conclusion of which a vote of thanks to Bro G Rowell the secretary of the original committee upon whom has fallen the brunt of the work in connexion with the preliminary organisation of the Lodge was received with acclamation and ordered to be entered on the minutes Bro A L Achard was temporarily appointed Preceptor The St Luke's Medical Lodge of Instruction proposes to meet on each Monday in the month from October to May inclusive with the exception of Mondays falling in the Christmas vacation Easter Monday, and Whit Monday The secretary is Bro J Eyre of Embankment-chambers, Villiers street W C

**Small pox Hospital at Barry** —The Barry (South Wales) District Council has resolved to erect a temporary small pox hospital at an estimated cost of about £1000.

**Health of Cardiff** —Dr E Walford, the medical officer of health of Cardiff reports that 5206 births were registered during 1901 corresponding to a rate of 31·4 per 1000 the deaths numbered 2596 being at the rate of 15·7 per 1000 Of the deaths small pox caused 1, measles, 3, whooping cough 86, diphtheria, 78, scarlet fever 29, and enteric fever 11 The birth rates and death rates were calculated on an estimated population of 165 308 inhabitants

**Eastern Dispensary, Bath** — The annual meeting of the subscribers of this institution was held on Jan 16th under the presidency of the mayor The medical report stated that 5026 patients had been treated during 1901 exclusively of 912 who had been attended at their homes The financial statement showed that the year commenced with an unfavourable balance of £61 and closed with a deficit of £19.

**Adulteration in Cornwall** —At the meeting of the General Purposes Committee of the Cornwall County Council held on Jan 14th it was stated that during the past five years 246 samples of milk were examined of which 57 were adulterated equal to a percentage of 20 7, in the United Kingdom the corresponding percentage was 10 5 The general percentage of adulteration in Cornwall was 11, against 9 1 in the country generally

**The Royal Institution** —The first Friday evening meeting at the Royal Institution in the current year was held on Jan 17th when Lord Rayleigh delivered an address on the Interference of Sound At the outset he said that his experiments and demonstrations would be made with very short sound waves even so short as to be inappreciable by the human ear because the limited space of a room was unfavourable for experiments with long waves He then proceeded to show a method of very easily measuring the length of very short sound waves When progressive sound waves met a flat surface they were reflected back and formed stationary waves consisting of 'loops' where there was to and fro motion of the air but no variation of pressure and nodes where there was variation of pressure but no motion At the loops a sensitive flame flared but at the nodes it was quiescent, at the loops sound was not perceptible to the ear, but at the nodes it was perceptible The distance between an adjoining loop and node was evidently half a wave length As the surface reflecting the sound was gradually withdrawn from the sensitive flame the latter alternately flared and was silent and when by the continued withdrawal of the reflector these alternations were repeated about ten times it was easy to calculate the wave length with an error of less that 1 per cent In this way the wave length produced by the bird call used to excite the flame in these experiments was shown to be two centimetres It excited the flame powerfully, but its sound was quite inaudible in the room, though when listened to close at hand it could be heard intermittently the sound being like the distant and faint squeak of a mouse or a bat A piece of steel which emitted a high note when struck was similarly tested and the wave length produced was shown to measure three centimetres Numerous experiments were shown illustrating the interference of the marginal and central portions of sound waves passing through circular apertures the best shape of foghorns for use at sea and the analogies of the interference of light and sound After the lecture the Duke of Northumberland as President of the institution unveiled a bust by the late Mr Onslow Ford of Sir Frederick Bramwell formerly secretary of the institution Sir James Crichton Browne as treasurer of the institution accepted the bust on behalf of the members and Sir Frederick Bramwell who said that he was well into his eighty fourth year expressed his acknowledgments

COUNTY ASYLUM, Chester.—Third Assistant Medical Officer, unmarried. Salary £160 per annum, with board, lodging, and washing.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary £150 per annum, with increase, and apartments, board, attendance, and washing.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—House Surgeon and Assistant House Surgeon. Salary, House Surgeon £100 per annum, Assistant £50 per annum, with apartments, board, and lodging.

DURHAM COUNTY ASYLUM.—Junior Assistant Medical Officer. Salary £140, rising to £160, with board, laundry, and attendance.

EAST SUFFOLK AND IPSWICH HOSPITAL.—Second House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ESSEX AND COLCHESTER HOSPITAL, Colchester.—Assistant House Surgeon (unmarried). Salary at rate of £50 per annum, with board, lodging, and washing.

FISHERTON ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

GENERAL HOSPITAL, Wolverhampton —Assistant House Physician, also Assistant House Surgeon, both for six months, with honorarium at rate of £70 per annum, and board, lodging, and washing.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL. -House Surgeon, unmarried. Salary £75 per annum, with residence, board, and washing.

HOSPITAL FOR WOMEN, Soho-square (The London School of Gynæcology).—Clinical Assistantships

HUNTINGDON COUNTY HOSPITAL.—House Surgeon. Salary £60 per annum.

KENT COUNTY ASYLUM, Barming Heath, Maidstone.—Fourth Assistant Medical Officer and Pathologist, unmarried. Salary £175 per annum, rising to £200, with quarters, attendance, &c.

LINCOLN COUNTY HOSPITAL.—Junior Male House Surgeon for six months, eligible for re-election. Honorarium of £25 for each period of six months, with board, residence, and washing.

LONDON HOSPITAL, Whitechapel, E.—Assistant Director of the Pathological Institute. Salary £200 per annum.

MONSALL FEVER HOSPITAL, Manchester.—Third Medical Assistant. Salary £100 per annum, with board and lodgings.

NEW HOSPITAL FOR WOMEN, 144, Euston-road, N.W.—Resident Medical Officer (female) for six months.

NORTH DEVON INFIRMARY, Barnstaple.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, N.E.—House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and laundry.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Surgeon to the Throat and Ear Department.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Resident House Surgeon. Salary £135 per annum, with board and residence.

QUEEN ADELAIDE'S DISPENSARY, Pollard-row, Bethnal Green-road, E.—Honorary Surgeon Dentist.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon for six months. Salary £50 per annum, with board, lodging, and washing.

ROYAL HALIFAX INFIRMARY.—House Surgeon, unmarried. Salary £120 per annum, with residence, board, and washing.

ST. MARY'S HOSPITAL, Paddington, W.—Casualty Physician. Salary £75 per annum.

ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Resident Medical Officer, unmarried. Salary £105, with residence and attendance.

SALFORD UNION INFIRMARY, Hope, near Eccles.—Resident Medical Officer. Salary £150 per annum, with apartments and attendance.

SEAMEN'S HOSPITAL SOCIETY (Branch Hospital, Royal Victoria and Albert Docks, E ).—House Surgeon. Salary £50 per annum, with board and residence.

STROUD GENERAL HOSPITAL —House Surgeon. Salary £80 per annum, with board, lodging, and washing.

VICTORIA CHILDREN'S HOSPITAL, Park-street, Hull.—Lady Assistant House Surgeon. Salary £40 per annum, with board and laundry.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Junior House Surgeon. Salary £50 per annum, with board, lodging, washing, and attendance.

WESTERN GENERAL DISPENSARY, Marylebone-road.—Honorary Surgeon.

WESTMINSTER GENERAL DISPENSARY.—Resident Medical Officer. Salary at rate of £120 per annum, with rooms, gas, coal, and attendance. Also Honorary Surgeon.

WREXHAM INFIRMARY.—House Surgeon. Salary £100 per annum, with board, washing, &c.

# Births, Marriages, and Deaths.

## MARRIAGES.

HARTLEY—WIMSHURST.—On Jan. 16th, at St. Mary's Church, Waterloo, Liverpool, John Hartley, M.B., Ch.B. Vict., to Edith Blanche, daughter of the late H. W. Wimshurst.

ROCHE—CRASKE.—On Jan. 22nd, at Borstal St. Matthew, Rochester, by the Rev. A. Cooper Marsden, B.D., Alfred R. Roche, B.A.Cantab., M.R.C.S., L.R.C.P., third son of Dr. William B. Roche, London, to Mary Louisa, eldest daughter of W. R. Craske, Esq., The Manor, Borstal, Rochester.

## DEATHS.

HILLS.—On Jan. 18th, at the Chantry, Norwich, suddenly, William Charles Hills, M.D. Aberd., aged 73.

WINGATE.—At Easington, co. Durham, suddenly, aged 38 years, Donald Wingate, M.B., C.M., Medical Officer for Easington Union. Friends please accept this intimation.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## ARTIFICIALLY MATURED (?) WHISKY.

*To the Editors of* THE LANCET.

SIRS,—Is not your whisky expert in THE LANCET of Jan. 11th, 1902, p. 109, just a little pessimistic—"cocksure" that "what is is best" in whisky? Discouraging, and therefore deterrent, to the patient experimenters who spend laborious hours (and sometimes brains) in trying to assist and hasten nature, by nature's own means, in improving whisky? Or does he hold a brief for the anxious whisky makers, who "carry stocks" of millions of gallons of this popular stimulant, and for whom "time means money" and quick maturation ruin? His facts are correct, but partial, and marshalled against progress. If German chemists had listened to similar warnings by interested parties the splendid success of artificial indigo production would not have been. But now it is the planters of nature's indigo who have the blue look-out. The blind supporters of time storage for maturing whisky may take a warning. Your author is right when he says that "countless attempts have been made," but wrong when he states that no real success has been attained (comparable with age) in improving and mellowing whisky. I admit that whisky would cease to be whisky if "fusel oil" (that bogie!), furfurol, and "probably other aldehydes" (his vague words) were removed. It is probable that the resultant spirit would be "wholesome," but no Scotchman would drink it. I admit that "those very products, raw, harsh, and disagreeable in young whisky," cause the seductive aroma, "gout," bouquet, "pleasing flavour," &c., which charm the appreciative drinker of old whisky. But I assert that it is not "time, and time alone," which works this happy change. Your author will, of course, know—what I merely state now for the benefit of those of "common and erroneous belief"—that whisky hermetically sealed in glass vessels is *not* changed, altered, improved, or spoilt by any lapse of "time, and time alone." This proves that *it is not time alone*, but some natural agency working through the wooden cask in time, which improves whisky and opens up a field full of promise for the inventive chemist. I have talked with the biggest producers and holders of Scotch whisky. They all frankly admit that a successful system of speedy maturation would be disastrous to them and sincerely wish failure to the inventor of any such process. It is obvious that to the holder of bonded whisky, staggering (financially) under the heavy stock he is carrying, any such successful system would spell ruin, or at least heavy loss. Good whisky does good to millions, and perhaps harm to a few. Bad whisky does nothing but harm to every poor wretch, black or white, who is fool enough to drink it. It is reasonable, therefore, that our Government should decide on a standard of quality before whisky is allowed to reach the public. But "time alone" should not be the test. The rich man can afford to pay the high price necessary for old whisky which has been nursed for years in expensive storage with all the consequent cost and loss. The poor man who likes whisky will be the *immediate* direct gainer by any successful system of speedy maturation. In Switzerland and Russia this is already accepted and practised. Their chemical and expert tests are very stringent, but "time" is not insisted upon nor any special process. Results alone are approved and passed, and the public safeguarded. Machines and processes are now in use in France, Russia, and Switzerland by distillers whose name is their most valued asset, and which quite satisfy the Government requirements. This does not please *our* whisky holders who press "time and time alone" on our Government as a safeguard, but it encourages diligent inquirers and inventors. o up-to date whisky chemist proposes to "eliminate" or "chemically abstract" the "raw bodies" which make the whisky, but even your author will surely allow him to assist nature's agencies *if* the result passes the judgment of the gourmet, the connoisseur, and the chemist This is simply making *old whisky* in a short time, and this can be, and is being, done, as your author may see if he communicates with me. The last sentence of your article seems peculiarly unfortunate. When one recalls the vast strides made in recent years by original thinkers, inventors, and chemists (names are needless) in surgery and medicine, it seems ungraceful to smite the humble experimenter in whisky who is working for the good of his fellow men and a living. He might shrewdly retaliate without being so arrogant as your writer who says: "Such artificial preparation can *never* be looked upon as fit to replace the spirit mellowed by age, and *any attempt to substitute it is to be deplored* and *certainly on medical grounds to be discountenanced strongly*." The italics are mine. I inclose my card.

I am, Sirs, yours faithfully,

Jan. 15th, 1902. $H_2O$.

*** We adhere to our opinion. Nothing will convince us that "old whisky" can be made "in a short time."—ED. L.

## A CHANGE OF UNIFORM.

MEMBERS of the Greenwich Union Board of Guardians have been, according to their various senses of humour, amused or shocked of late by the reported appearance of nurses in kilts at a fancy dress ball. Some members of the body declared that the wearing of kilts merely change in this direction would be useful, inasmuch as it would keep all matters of administration in one department. It was quite clear, too, that there was room for an amendment of the law which would enable local authorities in carrying out their re-housing schemes to build shops and clubrooms as part of, or attached to, the buildings which they proposed to erect. The suggestion had been frequently urged by local authorities, and he thought that its adoption would be of some benefit to them.

At the close of the debate a division was taken in which Dr. MACNAMARA's amendment was rejected by 30 votes.

### MONDAY, JAN. 20TH.

#### *The Small-pox Hospital Ships in the Thames.*

Lieutenant-Colonel TUFNELL asked the President of the Local Government Board whether his attention had been called to the continued increase of small-pox on the Essex coast near Purfleet; and would he state what steps the Government proposed to take to cause the immediate removal of the small-pox hospital ships now moored there.—Mr. J. A. PEASE asked the right hon. gentleman whether he was aware that the medical officer of health for the county had reported that the recent outbreak of small-pox was attributable to the presence of these vessels, and had recommended that they should be withdrawn from the precincts of the Essex coast.—Mr. LONG replied: I am not aware of that fact, but there is no dispute as to the fact that the presence of the small-pox hospital ships must cause some infection. In answer to my hon and gallant friend I have to say that I am aware of the occurrence of small-pox on the Essex coast, and have caused a medical inspector to communicate with the local authorities in the districts concerned. As regards the second part of the question, the managers of the Metropolitan Asylums District are doing everything in their power to provide the hospital accommodation necessary for the reception of small-pox cases from the metropolis; but, looking to the large number of these cases, I do not in the present circumstances propose to interfere with the discretion of the managers as to the use of the ships to which my hon. and gallant friend refers, and which have been moored in the Thames since 1885. It is impossible to select a place either for ships or hospitals on land which would not be in some degree exposed to the same drawbacks. But the managers are doing their utmost to deal with the serious epidemic and I cannot, in the present circumstances, recommend that the ships should be removed.—Mr. D. J. MORGAN asked whether the ships could not be moved further down the river to a point where there was practically no population on either side.—Mr. LONG: I cannot answer that question definitely, but I can say that every possible trouble has been taken to find another mooring place. As my hon. friend knows it is necessary that there should be communication with the shore so that patients may be easily taken to the vessels, and at present we have not been able to suggest any new place. I will, however, take into consideration any definite suggestion my hon. friend may like to make.—Mr. BARTLEY: Do the Government contemplate any legislation in view of this epidemic?—Mr. LONG: No, sir; no legislation is necessary, that I am aware of, of any kind.

### TUESDAY, JAN. 21ST.

#### *Vaccination Proceedings.*

Mr. LOGAN asked the Secretary of State for the Home Department if his attention had been directed to proceedings in the North London Police court on Jan. 11th, when an application was made for a certificate of exemption under the Vaccination Act, 1898, and refused, apparently on the ground that the applicant declined to enter into a discussion with the presiding magistrate; and whether he proposed to take any action in the matter.—Mr. RITCHIE replied: I have seen a newspaper cutting which the hon. Member has been good enough to send me. The law is that a person is not entitled to exemption unless he satisfies the magistrate that he conscientiously believes that vaccination would be prejudicial to the health of the child in question. I gather from the newspaper cutting that the applicant in this case did not so satisfy the magistrate. There are no steps which I can take in the matter.—Mr. LOGAN: Is it not enough for the applicant to say that he conscientiously objects to vaccination?—Mr. RITCHIE: I cannot enter into the mind of the magistrate. It is the magistrate who is to be satisfied, not I.

#### *The Government and the Early Closing of Shops.*

Mr. BALFOUR, in reply to a question addressed to him by Sir CHARLES DILKE, said that the subject of the early closing of shops had been under the consideration of the Government, but having regard to the other work which would come before the House they could not hold out any hope of legislation with reference to it during the present session.

## BOOKS, ETC., RECEIVED.

ARNOLD, EDWIN, 37, Bedford street, Strand, W.C.

Human Embryology and Morphology. By Arthur Keith, M.D. Aberd., F.R.C.S. Eng. Price 12s. 6d. net.

Manual of Alcoholic Fermentation and the Allied Industries. By Charles G. Matthews, F.I.C., F.C.S., &c. Price 7s. 6d. net.

DOIN, OCTAVE, 8, Place de l'Odéon, Paris.

Leçons sur les Maladies du Système Nerveux (année 1897-1898). Par F. Raymond, Professeur de Clinique des Maladies Nerveuses à la Faculté de Médecine de Paris. Recueillies et publiées par le Dr. E. Ricklin. Quatrième série. Price 15 francs. Ditto, année 1898-1899, cinquième série, price 16 francs.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BANNISTER, W. J., has been appointed Junior House Surgeon to the Macclesfield Infirmary.

BEDFORD, G. H., L.S.A., has been appointed Medical Officer of the Rothbury Union.

DENT, HOWARD, M.B. Durh., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Wolverhampton and Staffordshire General Hospital.

ERSKINE, A. M'C., M.B., B.Ch. R.U.I., has been appointed Medical Officer to the Goole Urban Council and Superintendent of the Fever Hospital at Goole.

GOVER, J. MAXWELL, M.B., B.S. Durh., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Gosforth District of the Castle Ward Union, Newcastle-upon-Tyne.

GREENWOOD, C. H., M.B., Ch.B. Vict., has been appointed Resident Casualty Officer to the Leeds General Infirmary.

JACKSON, ARTHUR M., M.D. Oxon., M.R.C.S., has been appointed Medical Superintendent of the Notts County Lunatic Asylum.

LITTLEWOOD, J. O., M.R.C.S., L.R.C.P. Lond., D.P.H., has been appointed Visiting Medical Officer to the Nottingham and Nottinghamshire Sanatorium for the Treatment of Consumption, Sherwood Forest, Mansfield.

O'CONNOR, J. E., M.B., B.S. R.U.I., has been appointed Medical Officer of Health for the Urban District of Wigston.

THOMPSON, WM. ATKIN, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Rochdale Infirmary.

WALLIS, C. EDWARD, M.R.C.S., L.R.C.P. Lond., has been appointed Dental Surgeon to Rochester House Asylum under the Metropolitan Asylums Board.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BOLTON INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £80 per annum, with apartments, board, and attendance.

BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, single. Salary £100 per annum, with board and residence.

BRECON INFIRMARY.—Resident House Surgeon, unmarried. Salary £100 per annum, with apartments, board, attendance, fire, and gas.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

CORPORATION OF LONDON.—Female Sanitary Inspector. Salary £125 per annum, rising to £150.

was to be tied round the patient's neck and the intestines of the sheep attached to the soles of the feet. This was done: in a couple of hours no trace of the fever remained. The charm and the intestines were then burned." Of course, with no definite knowledge of the nature of the charm we cannot discuss this therapeutic triumph. At first sight it would seem simpler to place the intestines round the neck and the charm somewhere else. We are inclined to believe that the effect would have been much the same.

### A HOME WANTED.

*To the Editors of* The Lancet.

Sirs,—Can any medical man in the country recommend a respectable couple in a quiet secluded village who would be willing to take care of a gentleman, aged 42 years? The patient has a chronic skin disease (no discharge) and his faculties are much blunted, but though feeble minded he is rational and amenable. He was formerly in good circumstances and was decidedly a *bon vivant*, but is now reduced to penury. His friends would, however, be able to pay a moderate charge for his board and lodging, say, £1 a week. He is not a fit case for hospital or asylum, and his friends desire that he should be far away from London, where he is exposed to undesirable influences. Devonshire or Cornwall would be preferred, but any suitable place not less than 100 miles from London would do.

I am, Sirs, yours faithfully,

Jan. 22nd, 1902. *L.R.C.P. & S. Ed.*

### A QUERY IN ETHICS.

*To the Editors of* The Lancet.

Sirs,—Will you kindly let me know in your columns next week whether there is any ethical objection to a medical man writing to secretaries of assurance companies offering to act as medical referee?

I am, Sirs, yours faithfully,

Jan. 17th, 1902. Young Practitioner.

*** Yes, there is every objection.—Ed. L.

### THE OPEN-AIR TREATMENT OF TUBERCULOSIS.

*To the Editors of* The Lancet.

Sirs,—Is there any place where by giving an annual subscription a City Company could obtain two or three letters of admission per annum? Perhaps some of your readers could help me. Ventnor and Bournemouth both ask for payment from the patients in addition to a letter of recommendation. I am, Sirs, yours faithfully,

Jan. 20th, 1902. Thane.

### A RASH RESEMBLING THAT OF VARIOLA PRODUCED BY THYROID EXTRACT.

*To the Editors of* The Lancet.

Sirs,—Thyroid tabloids may, and do at times, produce a papular rash, which may possibly be mistaken for the early rash of variola, and more especially so if any backache or elevation of temperature is present. The rash is generally accompanied by much itching and lasts for about six weeks after the remedy is discontinued; it again reappears on resuming the remedy.

I am, Sirs, yours faithfully,

Putney, S.W., Jan. 15th, 1902. Albert S. Morton, M.D. Durh.

### ADMINISTRATION OF ANÆSTHETICS DURING LABOUR.

*To the Editors of* The Lancet.

Sirs,—Would some of your correspondents favour me with their views as to the best way of administering chloroform during labour when one is single-handed? This subject is one which receives little attention in text-books and I have not been able to obtain much information on the subject from this source.—I am, Sirs, yours faithfully,

Jan. 17th, 1902. M.D.

*** Our correspondent is referred to the report of the proceedings of the Leeds and West Riding Medico-Chirurgical Society (p. 230), where he will find a description of an instrument which was shown to the society by Mr. C. J. Wright.—Ed. L.

### MOTOR-CARS FOR MEDICAL MEN.

*To the Editors of* The Lancet.

Sirs,—Now that our profession is beginning to recognise that the motor-car is bound to supersede the horse for making our daily visits, especially in those cases where long country rounds are made, perhaps a few words of advice from one who has used a car ever since the Act of 1896 came into force may be of some service to intending purchasers. I have tried all kinds of cars and motor cycles, but for absolute reliability, quietness, and appearance I can recommend the "genuine geared Benz," either the 4½ or 7 horse-power; the former is quite sufficient where fairly level, the latter in hilly districts. A great point in favour of these cars is the very small amount of fuel they consume; my car, a 4½, runs from 60 to 70 miles on two gallons of petrol at a cost of 2*s.* 4*d.* The high speed vertical engine with its row of dirty lubricators is of no practical use to a medical man; besides, its appearance is against it. The inclined wheel steering may be very nice for touring, but a great disadvantage to a man who has to be getting continually in and out. A hood also is most comfortable, and should be on every car. To sum up, I give the Benz car the first place for:—(1) its reliability; (2) its slow-running engine; (3) its good appearance; (4) the small amount of petrol consumed; (5) its extreme quietness; (6) its comparative cheapness; and (7) the easy starting. The engine can easily be started without turning a hand or pulling at the flywheel by a very simple device. Any medical man contemplating buying a car who cares to drop me a line shall have any assistance I can give him with pleasure.

I am, Sirs, yours faithfully,

St. Albans, Jan. 20th, 1902. T. Prichard Roberts.

◆

*Oppressed.*—A district medical officer must attend a sick person on receiving the usual order to do so, even when the sick person does not seem to him to be a proper person for such relief; as, for example, in the case of a hired servant, a member of a club, or a person in receipt of other relief. He can, and indeed should, bring before the notice of the guardians on the earliest possible occasion—that is to say, at their next meeting—any circumstances that, in his opinion, disentitle the patient in question to medical relief; and it is the duty of the guardians not to order medical relief or any other form of parish relief in cases not properly the subject of such relief.

## Medical Diary for the ensuing Week.

### OPERATIONS.

#### METROPOLITAN HOSPITALS.

**MONDAY** (27th).—London (2 p.m.), St. Bartholomew's (1.30 p.m.) St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynæcological, by Physicians, 2 p.m.), Soho-square (2 p.m.), Royal Orthopædic (2 p.m.), City Orthopædic (4 p.m.), Gt. Northern Central (2.30 p.m.) West London (2.30 p.m.), London Throat (2 p.m.).

**TUESDAY** (28th).—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (2 p.m. and 6 p.m.), Royal Ear (3 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden-square (9.30 a.m.).

**WEDNESDAY** (29th).—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing-cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopædic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond-street (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (2 p.m.), Cancer (2 p.m.), Throat, Golden-square (9.30 a.m.).

**THURSDAY** (30th).—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing-cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho-square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Gt. Northern Central (Gynæcological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (2 p.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden-square (9.30 a.m.).

**FRIDAY** (31st).—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing-cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Gt. Northern Central (2.30 p.m.). West London (2.30 p.m.), London Throat (2 p.m. and 6 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden-square, (9.30 a.m.), City Orthopædic (2.30 p.m.).

**SATURDAY** (1st).—Royal Free (9 a.m. and 2 p.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing-cross (2 p.m.), St. George's (1 p.m.), St. Mary's (10 p.m.), London Throat (2 p.m.), Throat, Golden-square (9.30 a.m.).

At the Royal Eye Hospital (2 p.m.), the Royal London Ophthalmic (10 a.m.), the Royal Westminster Ophthalmic (1.30 p.m.), and the Central London Ophthalmic Hospitals operations are performed daily.

### SOCIETIES.

**MONDAY** (27th).—Society of Arts.—8 p.m. Dr. S. Rideal: The Purification and Sterilisation of Water. (Cantor Lecture.)

Medical Society of London (11, Chandos-street, Cavendish-square, W.).—8.30 p.m. Discussion on The Nature and Treatment of Obesity (opened by Sir T. Lauder Brunton). (Council Meeting Night.)

Odontological Society of Great Britain (20, Hanover-square, W.).—7 p.m. Council. 8 p.m. Communications:—Mr. E. B. Dowsett: Sections of a Human Tooth showing Plici-Dentine (?).—Mr. C. W. Glassington: A *Composite Odontome.*—Mr. F. W. Collingwood: A Slight Modification of Patterson's Prolongation Apparatus.—Mr. E. Lloyd-Williams: A Fatal Case of Alveolar Abscess.—Dr. E. A. Peters: Suprarenal Extract in Dental Surgery.

**TUESDAY** (28th).—Royal Medical and Chirurgical Society (20, Hanover-square, W.).—8.30 p.m. Adjourned Discussion on Dr. S. M. Copeman's paper on Modern Methods of Vaccination and their Scientific Basis. Dr. *Greenwood,* Dr. S. *Coupland,* Dr. L. Parkes, Dr. Eddowes, Mr. H. A. Stonham, Dr. A. T. Cope, and Dr. J. Loane will take part in the discussion.

**WEDNESDAY** (29th).—British Balneological and Climatological Society (20, Hanover-square, W.).—8.30 p.m. Dr. I. Murray: Note on Hayling Island. Paper:—Mr. W. Armstrong: Adjuncts to Spa Treatment.

showed what a strong hold Scotch sentiment had, while the chairman, Mr. Donald McCall—whose name certainly suggests a kilty sympathy—gravely declared that he was not prepared to admit that the wearing of kilts was an act of indecency. It certainly is a novel theme—the indictment of women for wearing a skirt. Prudery has shrunk from a Scottish piper, but we always imagined that even Mrs Grundy would tolerate a female under similar circumstances and garments The matter eventually dropped—perhaps with the hope that to some extent the kilts would do likewise.

## POOR-LAW MEDICAL OFFICERS' SUPERANNUATION.

*To the Editors of* THE LANCET.

SIRS,—As a subscriber to THE LANCET for 38 years I shall feel extremely obliged if you will kindly give me some information in the following matter. I have been medical officer of a district of a union for 31 years. My age limit will be up in June which will make the service nearly 32 years. My subscription to the Poor-law Officers' Superannuation Fund has been deducted every quarter from my salary since the formation of the fund What I should like to know is, is the pension reckoned on the salary only and how much percentage, or on the emoluments altogether, such as salary and vaccination and lunacy fees combined ?

I am, Sirs, yours faithfully,

Jan 20th, 1902. G. P.

*** The superannuation is reckoned on the "salary or wages and emoluments" "Emoluments" are defined as "all fees, poundage, and other payments made to an officer as such; also the money value *of any apartments, rations, or other allowances in kind appertaining* to his office" Vaccination fees are not due to our correspondent as a district medical officer. They are paid to him as a public vaccinator under a contract which is not necessarily connected with his position as a district medical officer. For this reason vaccination fees have been considered not to be emoluments, and the superannuation deduction has not been made from them They will therefore not be included when the calculation of the superannuation amount is made. "G. P." having had more than 15 years' service at the time of the passing of the Act would be charged 3 per cent. on his salary and emoluments. In the latter lunacy fees and extra-medical fees certainly should be included.—ED L

## MEDICAL AID ASSOCIATIONS AND THE GENERAL MEDICAL COUNCIL.

*To the Editors of* THE LANCET.

SIRS,—I am glad that your correspondent Mr. Harry Clough in THE LANCET of Jan. 18th, p 207, appreciates my kindness and recognises my rapidity of perception and lucidity of expression. Such an appreciation tempts me to epitomise and to criticise further his arguments. I quite believe that he did not wish to provoke *argument with me, for I believe he was unaware of my existence,* but he must not take exception to my pleading a different opinion to himself *re* the action of the General Medical Council and giving expression to it If his letter did not invite criticism, why, then, did he take the trouble to have it inserted? I fail to see the application of the argument *re* a works club. A club of this description is a very different thing to a medical aid association, as I will endeavour to point out Workpeople may be taken to mean persons who are able-bodied or it is presumed they would not be at work. This means less attendance and more time *for* each individual case The fact that they are able to work is a certain guarantee as to health. Works clubs are usually composed of men and there is the chance of private attendance on their families In a medical aid association there is smaller remuneration, members and families are admitted without any guarantee as to health, they sweep in all and sundry, people who are able to pay and people afflicted with chronic illness or at least in doubtful health. Anyone who has had charge of a large works club, say, of 1000 members and a similar number of medical aid patients knows the relative amount of attendance demanded by each. Again, the money collected from the workpeople is deducted from their wages at the pay office and remitted to the medical officer with in some instances a small deduction for collection—in the case *of the medical aid association a large company prostitutes the services* of professional men for its own gain and as a bait for insurance of a questionable kind. In the one case there is canvassing from door to door, but this is not so with a works club Now, I ask, is it common sense to allow the profession to be cheated out of a large portion of its legitimate earnings to support such an organisation? I assert that the unqualified assistant has not been replaced by the unqualified medical student—the fully-qualified medical man has taken his place except in rare instances. I hold all collective physicking to be dishonourable and degrading, both to the profession and to the public. I classify as humbug the professing to do an impossibility—and it is a physical impossibility to do more than a given number of cases in a given time; that is, to do them properly. There may be many deserving cases in the medical aid association, but there is also a large proportion of cases that are not. Is the medical man to suffer for the luxury of these people and provide them with medicine and attendance at a penny and a halfpenny a week when they can pay from eighteenpence to 4*s* a week for organs, pianos, bicycles, phonographs, and other articles not strictly necessary to their well being? There is no wage-limit. Is it common sense to hold a club of this description? As to the General Medical Council, if your correspondent will take the trouble he will see that the general practitioner is very well represented for two reasons. There are Direct Representatives who are, or have been, general practitioners. There are University Representatives who will keep up the status of the profession in order to make it more attractive and so induce more men to enter. I maintain that the Council has acted in the best interests of the profession and the public in prohibiting the association of medical men with insurance clubs Medical men are notoriously unbusinesslike, and I do not suppose that any other body of men would tamely submit to having their services exploited as we have done The care of the poor is in the hands of the State and should not be in the hands of self-interested lay associations who practise cheap philanthropy at the expense of the profession. Organisation is necessary all along the line and there is ample room for improvement in every direction If the General Medical Council makes its measures drastic the quicker will the reform be and the nearer the ideal. In days gone by men (and young ones at that) used to strive for ideals and revolutions were accomplished. Nowadays we are satisfied with any makeshift. I venture to predict that the Council will carry out its implied intentions and I know that the young practitioner will benefit amongst others. It is by organisation that we will accomplish reforms and not by submitting to the lay exploitation of our services and unfair competition. I will leave it to time to prove the truth of my remarks to Mr. Harry Clough. And I shall be glad if he will be good enough to write me 10 years hence, and then give me his opinion of medical aid associations formed on his experience in the interval. Apologising for having taken up so much of your valuable space,

I am, Sirs, yours faithfully,

Leicester, Jan 18th, 1902 JOHN MACCORMAC.

## EXCISION OF GASTRIC ULCER.

*To the Editors of* THE LANCET.

SIRS,—Can you inform me, through the medium of your "Answers to Correspondents," if there has been published in THE LANCET or elsewhere an article similar to that on page 86 of your issue of Jan. 11th, 1902, only in regard to perforating gastric ulcer, where the ulcer has been excised.

I am, Sirs, yours faithfully,

Jan 20th, 1902. E. N. B.

*** A paper by Mr. R F. Jowers, which appeared in THE LANCET of March 2nd, 1895 (p 544), narrated a case under his own care and gave a table of cases under the care of other operators Since the date of this paper numerous instances have been recorded —ED L.

## FEES FOR INSURANCE EXAMINATIONS.

*To the Editors of* THE LANCET.

SIRS,—I am not fond of controversy in print at any time and least of all with an opponent who skilfully and wisely conceals his identity behind a *nom de plume;* but as some of your readers may be misled by *the latest contribution on* this subject, I *venture to ask space for* a brief reply, promising that I shall not trouble you further. If "Vigilans" has 'sometimes" had fees of any kind from this company, he must hold a letter of appointment which stipulates that the minimum fee payable for an examination is 10*s* 6*d*., but even if it had been true that he had 'sometimes received 5*s*," that would at least involve complicity on his part in the arrangement, and therefore he would have had no right to complain To slightly paraphrase your correspondent's own words, "It does seem strange that while holding a company's appointment and receiving its fees, he should be conspicuous (as far as a *nom de plume* will admit of this) in endeavouring to injure it." The fee that I have already discussed has related to sickness insurance alone, and is of course, often exceeded. Some annual premiums are as low as £1 2*s*. 10*d*. per annum, and there are no large premiums as in life assurance to equalise matters. Our critics, I think, should in common fairness compare the fee we offer with that paid by friendly societies whose business also is sickness insurance. Comparison, I apprehend would not be unfavourable to us.

I am, Sirs, yours faithfully,

HENRY BROWN,

Jan. 22nd, 1902 Manager, Century Insurance Company, Limited.

## *HONOURS TO EDWARD JENNER A HUNDRED YEARS AGO.*

*Bonner and Middleton's Bristol Journal*, afterwards the *Bristol Mirror*, of Jan. 16th, 1802, contains the following:—

> "The Royal Economical Society of Madrid has admitted into its bosom, with the title of Associates of Merit, Count Rumford and Dr. Jenner, the inventor of vaccine inoculation."
>
> "A subscription has been commenced in Gloucestershire, patronised by many noblemen and respectable gentlemen of that county, for presenting Dr Jenner with a piece of plate for his discovery of vaccine inoculation The subscription already exceeds £300."

## A RAPID RECOVERY.

FROM a letter in the *Daily Dispatch* we gather some details of a "cure" as remarkable in its method and prompt results as we fear it is unlikely to be available in genuine cases of typhoid fever. "A young lady in a west-country town was ill with typhoid fever—so ill that hope of recovery had been abandoned by the doctor. Her father consulted an old woman in a village five miles distant with a reputation for cures She gave him a charm and told him to obtain certain portions of the intestines of a newly slaughtered sheep The charm

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

**Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.**

**THURSDAY** (30th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos street, Cavendish-square, W.).—Cases and Specimens by Mr. Keeling, Mr. Hickman, Mr. Roll, Mr. Ormond, Mr. Parsons, and Mr. Taylor. Papers:—Dr. C. O Hawthorne: On Intra cranial Thrombosis as the Cause of Double Optic Neuritis in Cases of Chlorosis —Dr G. A Berry: (1) On so called Muscular Asthenopia, (2) Note on the Treatment of Cystoid Cicatrix following Cataract Extraction —Mr S Snell: (1) Tumour of Orbit occasioning a peculiar Varicosity of Vessels on the Surface of the Eyeball; (2) Ringworm of the Eyelids in an Adult due to a Large-spored Tricophyton —Dr F W. ## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY** (27th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C )—4 P.M. Dr. G. Little: Clinique (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W ).—5 P.M. Mr. Baldwin: Surgical Emergencies.

**TUESDAY** (28th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—4 P.M. Dr. J. Taylor: Clinique. (Medical.)

POST GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Bidwell: Plaster of Paris Splints

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury)—3 30 P.M. Dr. Tooth: Paralysis of the Cranial Nerves.

**WEDNESDAY** (29th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C ).—4 P.M. Mr. J. Berry: Clinique (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. McAdam Eccles: Lantern Demonstrations in Hernia.

**THURSDAY** (30th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W C )—4 P.M. Mr. J. Hutchinson, jun.: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M Mr. Edwards: Rectal Fistula

CHARING-CROSS HOSPITAL.—4 P.M. Mr. S. Boyd: Surgical Cases. (Post-Graduate Course.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond street, W.C.).—4 P.M. Dr. Kellock: Tortocollis.

**FRIDAY** (31st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C )—4 P.M. Dr. D Grant: Clinique. (Ear.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Shuter: Preparation of Patients before an Anæsthetic

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice.

---

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only.* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

---

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol II of 1901, which was completed with the issue of Dec. 28th, and the Title-page to the Volume, were given in THE LANCET of Jan 4th.

---

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

---

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year .. .. .. | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months . .. ... | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months .. ... | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

---

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

**During the week marked copies of the following newspapers have been received:**—*Heraldo de Madrid, Meath Herald, Folkestone Telegraph, Hartlepool Mail, Brighton Gazette, Kent Examiner, Suffolk Chronicle, Sheffield and Rotherham Independent, Surrey Advertiser, Local Government Journal, Bristol Mercury, Dublin Express, Darlington Star, Citizen, Scotsman, Times of India, Pioneer Mail, Huddersfield Examiner, Sanitary Record, Local Government Chronicle, Mining Journal, Merthyr Express, Hertfordshire Mercury, Burton Chronicle, Glasgow Herald, [illegible] Advertiser, West Sussex Gazette, Lincolnshire Advertiser, Dorking Advertiser, Bolton Chronicle, Liverpool Mercury, Manchester Evening Mail, Kent Messenger, Middlesbrough Gazette, Birmingham Post, Aberdeen Free Press, Yorkshire Post, Cardiff Mail, Sheffield Independent, Sussex Daily News, [illegible] Gazette, Wiltshire Herald, Bradford Observer, Morning Post, Essex Herald, Birmingham Argus, Newcastle Journal, Cambria Leader, Hereford Mercury, Exeter Times, Penrith Observer, Daily Graphic, Cambridge Chronicle.*

the sternum, and in the fifth space the hepatic dulness alters the note, but in the fourth space the dulness of the right auricle is present for about one finger-breadth in an adult and rather less in the child. When the auricle is dilated it may extend to two finger-breadths in the fourth space and from a half to one finger-breadth in the third. When the dilatation is very great it may amount to three finger-breadths in the fourth space, one and a half in the third, and may even be detected in the second. The accurate determination of the size of the right auricle is a matter of the greatest importance and often indicates at once the necessity for leeches to relieve distension. Yet there is no part of physical examination which is so universally and systematically neglected and the patient is too often allowed to suffer cardiac distress when he might be relieved in a few minutes. The suffering due to a distended bladder a medical man would promptly relieve, but that due to a distended right heart is allowed to remain because his percussion is not accurate and bleeding is out of fashion. Recently when I advised a practitioner in charge of a case of pneumonia to try the effect of a few leeches he replied that he would "see if they could be obtained in the neighbourhood." Evidently the distended right hearts of this gentleman's patients got no relief.

You have now determined the most important facts about the heart, its size and strength, and your stethoscope is still in your pocket But by this time you and the child are on good terms and you may quietly produce it without alarming him. It should be flexible and binaural; the rigidity of the old wooden instrument makes its use difficult in the child and you are apt to press too heavily with it. Avoid the cumbersome instruments with a spring; all that you want is a small and simple ivory cup as a chest-piece with two rubber tubes from it to two ivory ear-pieces. If these fit the ears properly there is no need for any spring. This more simple instrument is better for your purpose, for it makes no artificial noises of its own and it is less alarming to the child. If the latter shows any sign of fear it may be well to let him have it in his hands for a minute or two and look upon it as a new kind of toy before he is made the subject of its scientific application.

In auscultating the heart of a child be on the look-out for murmurs due to congenital malformation. Very peculiar some of them are, and sometimes very puzzling. The most frequent, I think, is a systolic murmur, often very loud, which is loudest at, or just below, the junction of the left fourth costal cartilage with the sternum; it is probably often due to an incomplete cardiac septum. The next most common, perhaps, is a systolic murmur over the pulmonary artery, loudest at the second left cartilage and conducted towards the clavicle, often audible in one or both supra-scapular fossæ. This indicates a congenital obstruction of the pulmonary artery. It is often impossible to diagnose the exact condition of a malformed heart by physical examination, and in some cases there may be no murmur at all. A patent foramen ovale, unassociated with any other malformation, is probably of little importance and is a doubtful cause of murmur. Congenital murmurs are systolic in time; a presystolic or diastolic congenital murmur is exceedingly rare. Congenital malformations of the heart mainly affect its right side, which has the predominance in activity during intra-uterine life. After birth this side has much less proneness to disease than the left, though the tricuspid valve does not always entirely escape in rheumatism. But the most important affection of the right heart clinically is secondary to acute or extensive chronic disease of the lungs or to disease of the left heart. In all such conditions a careful watch should be kept on the amount of distension of the right auricle Think of the tremendous strain on the right heart which a pneumonia causes even within two or three days. The thin-walled auricle becomes greatly distended and the stronger ventricle shares to a less extent in the distension. If the auricle did not act as a reservoir the ventricle would soon be over-distended and its action brought to a standstill. To some extent, then, the dilatation of the auricle is conservative. but if it exceed a certain amount the border-line which separates safety from danger is easily crossed. Distress and dyspnœa are experienced, and the right ventricle has greater and greater difficulty in expelling its blood. If at the same time its muscular structure is poisoned by pneumococcal toxins we can easily understand that, even in a child with healthy heart, liver, and kidneys, a pneumonia is a process dangerous to life. It is true that the child has a much better chance than the adult of weathering the storm, yet its violence may be much diminished and the patient often very obviously relieved by applying a few leeches over his liver. Not only are the distress and dyspnœa diminished, but the patient is enabled to sleep. When the right heart is over-distended sleep is much disturbed and may be impossible. Relieve the over-distension by a few leeches and the patient falls asleep without any hypnotics Within a short time after the bleeding you will find on careful percussion that the dulness in the fourth right space has diminished, often by as much as a finger-breadth. The relief will almost certainly last for two days, perhaps longer. But do not forget to percuss out the auricular dulness every day. If the pneumonia continues to increase it may be necessary to repeat the leeches in two or three days; in a few cases of exceptional severity (and pneumonia in children under two years of age is not infrequently fatal) it may be advisable to use them even a third time. And in considering the question of bleeding in pneumonia remember that pallor of face and smallness of pulse are not necessarily contra-indications, for after the right side has been relieved the pulse will be stronger and the colour of the cheeks improved. You will observe this if you watch carefully the effect of the application of leeches in such a condition.

What has been said about the importance of carefully ascertaining the amount of distension of the right auricle in pneumonia applies also to certain other pulmonary affections. In acute bronchitis, in chronic bronchitis with an acute exacerbation, in whooping-cough with its mixture of collapse, broncho-pneumonia, and emphysema, and in an asthmatic attack it is important to notice the amount of distension of the right auricle. It is true that the determination may be difficult if the anterior base of the right lung is emphysematous or consolidated, and it may sometimes be impossible when there is fluid in the right pleural cavity, but in the great majority of cases of pulmonary disease it can be accomplished. In all cases of disease of the left heart, especially when it has been injured by rheumatism, it is extremely important to note carefully the amount of distension of the right auricle. It is not usually possible to detect in a primary rheumatic attack an acute dilatation of the right heart, such as seems to occur invariably in the left ventricle. Nor is it dilated in a first attack of chorea, while the left ventricle almost always is. Even when the rheumatic process has damaged the left ventricle sufficiently to interfere with its suction-action, and thus to raise the tension in the pulmonary artery, the only physical sign which reveals this is the accentuation of the pulmonary second sound. For a considerable time the right ventricle will succeed in overcoming the increased tension without affording any clinical evidence of hypertrophy or dilatation; but if the primary rheumatic attack has been very severe, or if a relapse occurs (and to this rheumatic children are exceedingly liable, especially when they are deprived of salicylates), and there is evidence of pericarditis or of great dilatation of the left ventricle, then expect to find a gradual increase in the size of the right auricle. Watch it carefully. If the dilatation of this structure is rapid dyspnœa and cardiac distress will probably be present, but a more gradual increase will only be revealed by percussion. As time passes the heart accommodates itself as well as it can to its difficulties, and if the rheumatism does not recur a condition of comparative comfort may be attained in which the right auricle is distinctly dilated but not yet grievously hampered by distension. The dulness in the fourth right space may amount to one and a half or two finger-breadths, and yet there is no call for relief by leeches. It is, however, a condition of unstable equilibrium. A fresh rheumatic attack or a little over-exertion may turn the scale. Increased dyspnœa reveals the greater strain; the auricle dilates further and its dulness may amount to two and a half or even three finger-breadths in the fourth right space, one and a half in the third, and half a finger-breadth in the second Before this the liver has become considerably enlarged. If you find it down to the umbilicus or even lower and the amount of urine passed be decreasing there is no time to be lost. The condition is a dangerous one, but relief may be given by prompt venesection or leeching. The auricular dulness will then be found to diminish; the liver also will be smaller, and the digitalis, which was producing little or no effect before, will manifest its action. Hypodermic strychnine will assist in restoring compensation. It is surprising to see how much relief may be given in the later stages of rheumatic heart disease by

# A Presidential Address

ON

# THE HEART OF THE CHILD.

*Delivered before the Harveian Society of London on Jan. 16th, 1902,*

BY D. B. LEES, M.A., M.D. CANTAB., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET; PHYSICIAN TO ST. MARY'S HOSPITAL; EXAMINER IN MEDICINE, UNIVERSITY OF CAMBRIDGE.

GENTLEMEN,—The laws of the Harveian Society of London require that at the conclusion of his year of office the President shall deliver an address. I ask your attention, therefore, for a few moments to a short study of a subject too much neglected—the heart of the child.

"The child's heart," said Dr. Sturges, in the Lumleian Lectures for 1894,[1] "*holds as many secrets as the man's* and is even more deceiving" If this be so it needs the more careful study and (even more than the heart of the adult) demands accurate investigation and patient observation. Yet who thinks it worth while to spend much time in examining the heart of a child? Does every medical man investigate the condition of this organ in each child patient as carefully as he does in an adult? In how many instances does he even recognise that it is his duty to examine it? Doubtless he feels the child's pulse, but does he bestow much care upon the investigation of the heart itself? Does he always remember that heart disease is frequent in early life, that its beginnings may easily be overlooked unless he is careful, and that his neglect to ascertain the exact condition may be disastrous to the whole of the child's future? Think of the amount of work which the child's heart will have to undertake. Calculating at the rate of one beat per second, which is below the truth, it will have to contract no less than 31,536,000 times every year. If it survive for 50 years it will have performed the enormous number of 1,576,000,000 of beats And if we adopt the estimate of Dr. Leonard Hill in the second volume of Schäfer's "Physiology," that the human heart performs work to the amount of 1000 kilogramme-metres every hour, we find that in a year its total work will be 8,760,000 kilogramme-metres, and in 50 years 438,000,000 kilogramme-metres. Translating this into English measures we find that during these 50 years the heart will have to lift 1,500,000 tons to a height of one foot. That is the work which lies before the child's heart if it survive through a life of 50 years. How can it possibly accomplish the task unless it is thoroughly sound and well? Remember, also, that the child's heart is an organ incompletely developed. It has to grow to its full size and to minister to a growing body. Any disease, therefore, which damages it not only hinders its future work but impedes its development and the development of the whole organism. From this point of view the integrity of the child's heart is even more important than that of the man's.

The child's heart can be examined by the same methods as are employed for that of an adult. In some respects it is even more accessible, for in the child there is no excess of adipose tissue, no great muscular development, no large pendulous breasts, and rarely any emphysema. If the practitioner is rough and awkward he may make difficulties for himself by exciting the child's fears, but anyone who knows how to deal with children can usually examine the heart of even the most "spoiled" child with accuracy. Impatient words, an ungenial aspect, hasty measures, or cold hands may make a young child cry and resist with all its might, but pleasant speech, a kindly manner, gentle ways, and warm hands will usually calm the most nervous child and allow of a complete examination, provided that the undressing is done by the mother or the nurse and that she stands by the bed while the examination is made.

The chest being thus exposed to view we notice at once whether there is any thoracic deformity or any prominence of the præcordial region and the position of any visible cardiac impulse. Having noted this, the first idea of most practitioners is to pull out a terrible-looking instrument called a stethoscope, which probably appears to the child a sort of pistol, and doubtless is going to hurt him not a little. This early recourse to the stethoscope is a great mistake for more reasons than one. Keep it in your pocket to the last. A child is accustomed to being handled; you may use your hands to examine him as much as you like if they are only warm and gentle. He will not object at all to percussion if it be done very lightly and with the fingers only, but he will not tolerate the forcible hammering which some medical men call percussion, and those illusory instruments known as pleximeters will certainly make him cry. Fortunately, what the child allows is exactly what the physician ought to use, the lightest possible percussion. It is this, and not the heavy thumping, which is to tell you the precise size of his heart. But first warm your hand and lay it gently over the præcordial region that you may feel the cardiac impulse and ascertain its strength and whether it is localised or diffused. This gives you information as to the strength of the left ventricle. Then shift your hand gently to the epigastrium and notice whether any impulse of the right ventricle is to be felt there; if so, either there is some congenital malformation or there is some disease of the lungs or left heart. Slide the hand further to the hepatic region and see whether it meets the resistance of an enlarged liver, and try very gently to feel its edge A single gentle tap on a finger below the costal margin will confirm or correct your observation.

Next proceed to percussion, but begin with a clear idea of the object of this measure and the way in which it is to be carried out. What is the object of percussion of the heart? To ascertain the superficial cardiac dulness, say the text-books. But what is the value of this result when you have obtained it? Almost nothing, from the cardiac point of view, though it may give valuable information about the left lung. What we really want to know and what can quite easily be ascertained is the exact size of the heart. We can, indeed, determine little or nothing by physical examination about the size of the left auricle, and we can form only an approximate opinion of the size of the right ventricle But the size of the left ventricle and that of the right auricle can usually be ascertained with very considerable accuracy. Let your pleximeter be the terminal phalanx of a finger of your left hand. Let this phalanx be pressed somewhat firmly, yet very gently, on the spot to be percussed, and let no other part of your hand touch the chest-wall. So you will avoid the conduction of resonance from elsewhere which is a fruitful source of fallacy. First select a spot in the mid-axilla and percuss here with the lightest possible stroke; then gradually shift your percussed finger towards the sternum and you will easily recognise the change of note when the border of the heart is reached. For though the *left lung partly overlaps the heart it is only by a thin layer*, and the margin of the heart is thick and airless and does not require what is called "deep" or heavy percussion to recognise it. Indeed, such percussion often defeats itself, for it introduces pulmonary and gastric resonance from a distance, especially if the whole of the percussed finger be applied to the chest-wall. Expect to find the cardiac margin a little to the left of the position of the impulse, for though it is usual to speak of the "apex-beat," it is not the extremity of the heart which strikes the chest-wall, but a spot *on the right ventricle at some little distance from that extremity*. The left border of the cardiac dulness in health extends a little to the left of the position of the impulse; when the heart is dilated this difference may amount to a finger-breadth or even more. (If anyone objects to the term "finger-breadth" as unscientific he may say instead "two centimetres," but he does not thereby make the measure more accurate, he only introduces a false idea of mathematical precision.) Next determine whether the dulness extends to the left of the nipple itself, and if so to what amount in *the nipple-acromial* line. Two points on the border of the left ventricle having been thus determined the line connecting them should correspond to this border, and this can easily be verified by holding the percussed finger parallel to this line. The difference in tone to the left and to the right of this line will then be obvious at once. Next determine the size of the right auricle. Very few percussors pay the least attention to this structure and many seem to be unaware of the fact that the dulness due to it may always be detected, even in the normal heart, in the fourth right intercostal space. The third space ought to be resonant quite up to which recovers completely, but evidence is accumulating to prove that there is usually very much more than this—that actual inflammation of the muscular substance and fibrous structures of the heart exists, and that this is caused by the local presence of a diplococcal micro-organism. Dr. Poynton and Dr. A. Paine have demonstrated such organisms in the cardiac valves (with intact epithelium) and in the muscular wall. The same investigators have proved that pericardial fluid from a rheumatic child when injected intravenously into rabbits can cause in these animals all the most characteristic effects of rheumatism in the child. They have also obtained from a rheumatic nodule in a child, carefully excised with aseptic precautions, a most abundant growth of the typical diplococci in pure culture. In rheumatism, then, we are dealing with an inflammation of the child's most important organ caused by the local presence of a pernicious micro-organism.

---

[1] THE LANCET, March 10th (p. [illegible]), 17th (p. 653), and 24th (p. 733), 1894.

The question of treatment at once divides itself into two problems: Can we by the administration of drugs directly destroy these microbes or arrest their growth and increase, without damage to the child? and have we any means of directly repressing the cardiac inflammation?

To the first question I reply that in sodium salicylate, in adequate doses, we have a drug which seems to be definitely antagonistic to the rheumatic process. The theory that it merely relieves pain is only possible when adults are the subjects of the disease; in the child it is at once seen to be absurd. The best proof of the genuine efficacy of salicylate in arresting rheumatism is found in the great tendency to relapse when the drug is being administered in doses which are too small, and especially when it is too soon given up. There is a widespread impression that salicylate of soda is "depressing to the heart." What is really depressing to the heart is the rheumatic microbe, its works and ways, and some of its pernicious effects have been attributed to the salicylate. Children bear salicylate well and it rarely causes in them the unpleasant aural symptoms which are common in the adult. It seems to be almost as necessary to a rheumatic child as mercury is to a syphilitic infant, and some children with great tendency to rheumatic relapse ought to take a small quantity of the drug daily for a long time. Sodium bicarbonate is another drug which seems to be certainly useful in rheumatism. It may be given in double the dose of the salicylate and along with it. My impression is that the acute dilatation of the left ventricle subsides more rapidly when the bicarbonate has been freely given than when the salicylate has been administered alone.

The question whether we have any means of repressing the cardiac inflammation may also be answered with confidence. Leeches will diminish the congestion of the cardiac vessels, even when applied over the liver, by lessening the pressure in the right auricle and thus aiding the escape of the blood in the coronary sinus and the intra-cardiac venules, and the local application of an ice-bag most certainly represses the cardiac inflammation These two remedies are of the greatest possible service to the rheumatic heart. Ice is undoubtedly depressing to the normal heart, but when preceded by leeches and used with care it is the reverse of depressing to the rheumatic heart. It relieves the depression caused by the rheumatism, and under its use I have often watched the dilated ventricle diminish and the feeble diffused impulse become changed into a steady, heaving, local thrust. Digitalis is of little service in the treatment of rheumatic cardiac inflammation in the child; its opportunity is later, when the inflammation has subsided and the mechanical effects of the cardiac lesions manifest themselves. Then it will work wonders. When we pass from inflammatory conditions of the heart to the ventricular dilatation and enfeeblement caused by toxæmia we see that leeches and ice are inapplicable. Digitalis is sometimes of service, but the hypodermic injection of strychnine is of still greater utility. Iron is of value in anæmic debility, but in diphtheria I rely mainly upon subcutaneous injection of atropine when danger threatens. I first employed belladonna in diphtherial paralysis more than 20 years ago on physiological grounds. It has subsequently been continually employed at the Hospital for Sick Children and I believe I have seen it save many lives. In cases of less urgency the drug may be given by the mouth, but where the dulness of the left ventricle extends more than one finger-breadth to the left of the nipple line it should be given subcutaneously, with a frequency regulated by the imminence of the danger.

It only remains for me to thank you, gentlemen, for the honour which you bestowed on me a year ago by electing me your president and for your kindness to me during my year of office. The election of that distinguished surgeon, Mr. W. Watson Cheyne, to be president for the next year is a most happy augury for a prosperous session.

---

# NOTES CONCERNING A NATIVE REMEDY FOR BLACKWATER FEVER.

By D. R. O'SULLIVAN-BEARE, M.B., B.Ch. Dub.,
HIS BRITANNIC MAJESTY'S VICE-CONSUL, PEMBA, EAST AFRICA;
HONORARY MEDICAL OFFICER, H.H. THE SULTAN OF
ZANZIBAR'S GOVERNMENT.

*With Note by* Mr. E. M. Holmes, F.L.S.

It needs no apology on my part for submitting to the notice of the medical profession some particulars concerning a native remedy which appears to be of real value in the treatment of hæmoglobinuric or blackwater fever—that most deadly of the maladies which attack Europeans in tropical Africa, and the one which is responsible for more deaths and for more invaliding amongst them than all the other diseases together. The remedy in question is indigenous to tropical East Africa, and the "wa-ganga," or native medicine men, claim for it that it is a true specific for blackwater fever. But before proceeding to set forth details concerning the remedy I may be permitted to offer a few remarks with regard to the fell disease for which it is said to be a cure.

The principal symptoms characteristic of an attack of blackwater fever are four in number—namely, heightened temperature, vomiting, jaundice, and dark-coloured urine. The dark hue of the urine, which in many cases is as black as porter, is due to the presence therein of hæmoglobin, or possibly methæmoglobin, and it is so striking a symptom that it has determined the popular name for the disease The starting-point of an attack of blackwater fever is a condition of general toxæmia. The toxin present in the system exerts a destructive action upon the red corpuscles, and the circulation in the blood plasma of the hæmoglobin thus set free is responsible for all the symptoms which characterise an attack of the disease. In the early stage of the condition of hæmoglobinæmia the liver deals with the free hæmoglobin, which it converts into bile pigments. But there is a limit to the capacity of the liver for thus acting, and when that limit has been reached any excess of free hæmoglobin is eliminated through the kidneys. The symptom of hæmoglobinuria is indicative, therefore, of a wholesale destruction of red corpuscles. The passage of the free hæmoglobin through the kidneys sets up a true nephritis, indicated by the fact that the urine soon becomes loaded with albumin, and in many cases the nephritis thus produced gives rise to suppression of urine, partial or complete, with resulting uræmia. Thus a person attacked by blackwater fever suffers at the same time from violent hæmorrhage and from profound depression of the nervous system, due to heightened temperature and to uncontrollable nausea and vomiting; superadded to which is the very grave condition of nephritis. It is obvious, therefore, that blackwater fever is one of the most formidable of all known diseases.

As to the primary cause of blackwater fever we are entirely in ignorance. The predisposing cause of the disease is undoubtedly that anæmic state of the system produced by repeated attacks of ordinary malaria which is known as malarial cachexia. With regard to the theory enunciated by Professor Koch, that the administration of quinine is the chief exciting or determining cause of an attack of blackwater fever, I would point out that the disease undoubtedly attacks native Africans who have never taken a dose of that drug; two such instances have come under my notice. Again, in Zanzibar and Pemba, where Europeans and natives alike suffer from all varieties of malaria and are habitually treated with quinine, blackwater fever is unknown, save in the case of those persons who have resided in or have visited districts on the mainland where the disease occurs.

Personally I hold that blackwater fever is not a complication of ordinary malaria, but an entirely distinct disease which at present is endemic in certain districts only; that it attacks persons exposed to its influence whose vital powers of resistance have become weakened from the effects of chill, insolation, bad or insufficient diet, over-fatigue, or possibly treatment of this kind and how long life may be preserved *even when the condition of the heart is such that the child* is incapable of exertion. But the fatal susceptibility to renewed attacks of rheumatism, incapacitating the heart still more, at last defeats the physician.

Before leaving the right side of the heart I must call your attention to a systolic murmur over the tricuspid region which is not very uncommon in healthy children. It is a low, soft, short murmur, best heard about halfway between the left edge of the sternum and the nipple line, and usually becoming inaudible at a short distance to the left of this line. It is sometimes accompanied by slight irregularity of the heart's action. Its site of maximum audibility is lower than that of the congenital murmur already described and to the right of that of a mitral murmur. It does not indicate any organic disease.

Let us now study the left side of the heart. The left auricle is inaccessible, but enlargement of the left ventricle (in which enlargement the right ventricle probably shares to some extent) can be easily determined by careful percussion, and the strength of the ventricular muscle can be fairly estimated by observing the force and localisation of the impulse.

Dilatation of the left ventricle being very common in children who are out of health it is important to start with a clear idea of the position of the left border of the cardiac dulness in a normal child Dr. F. J. Poynton determined *this carefully in 35 healthy public-school boys between the* ages of 12 and 14 years In 21 out of the 35 boys the left limit was about one inch internal to the nipple, in seven it reached a vertical line through the inner margin of the areola, in five it extended as far as the vertical nipple line, and in two it passed this line by three quarters of an inch and by one inch respectively. One of these two boys, however, was living in the medical attendant's house because he was delicate, the other had recently suffered from influenza Thus we may conclude that in healthy boys of from 12 to 14 years of age the left border of the cardiac dulness is found at about one finger-breadth internal to the nipple line. In a few it appears to reach this line, and this seems the more common in the younger children, especially before seven years of age. In 45 cases of children under 12 years old in the surgical wards of the Hospital for Sick Children Dr. Poynton found the left limit internal to the nipple in 19, in the nipple line in 18, and external to the nipple in eight. But of course these were not perfectly healthy children, for they were all inmates of surgical wards. We may conclude that in normal children the left border of the cardiac dulness is usually distinctly internal to the nipple line, that it may sometimes reach it, but that it rarely goes beyond it. This must be carefully remembered when we investigate the cardiac dulness in a child who is suffering from disease, for it is so common to find the left limit from a half to one finger-breadth external to the nipple line that we may be led to consider it as normal, and its discovery to be of no importance. But this inference would be false in fact as well as in logic; its commonness only proves that its causes are many. The cardiac muscle of the child is perhaps specially susceptible to the deleterious influence of toxins and poisonous products circulating in the blood.

The most characteristic instance of this is diphtheria, *which is much more fatal in children than in adults, sudden* death being by no means very rare after a severe attack of diphtheria in a child. The fatal issue is usually caused by extensive fatty degeneration and destruction of the cardiac muscular fibres, such as Dr Sidney Martin found to be caused in animals by injection of the diphtherial albumoses. In and after an attack of diphtheria in a child there is usually enlargement of the left ventricle, the impulse becomes diffused and weak, and the first sound is short and feeble. If the dilatation amounts to two finger-breadths to the left of the nipple line the danger of death is great and the case should be very closely watched. And if the limit of the dulness of the left ventricle is only one finger-breadth outside the nipple line it must be remembered that a rapid increase in the dilatation may occur, even six or eight weeks after the diphtherial attack, and may cause sudden and entirely unexpected death at a time when the practitioner is looking for convalescence and has given a hopeful prognosis. Influenza, *also, may produce a rapid dilatation of* the left ventricle which may be dangerous to life, but in this disease the susceptibility of the child seems to be less than that of the adult.

The pneumococcal toxin appears to affect the left ventricle *less than that of influenza, and though there is usually* some enlargement of the cardiac dulness to the left in pneumonia it is much less than the enlargement of the right auricle, and one is often doubtful whether the enlargement to the left may not be due to dilatation of the right ventricle pushing the border of the heart further to the left. The rapid recovery which often follows the crisis in pneumonia suggests that the poisonous influence of the toxin of the pneumococcus on the left ventricle cannot be very great

In typhoid fever a gradual enlargement of the left ventricle is usually to be detected, along with diffusion and weakening of the impulse: the first sound also becomes weak and short. The increase in size often reaches one finger-breadth outside the nipple-line and may amount to two finger-breadths. During convalescence the ventricle gradually returns to its normal size and its strength increases. In tuberculosis the left ventricle is frequently moderately dilated. How far this is due to a tuberculous toxin and how far merely to general debility and anæmia it is impossible to say. Even in debility and in anæmia there may be poisonous products of perverted metabolism circulating in the blood, and in renal disease it is quite likely that some of the increase of the dulness of the left heart may be due to toxæmia as well as to the influence on the ventricle of the raised arterial tension.

In acute and subacute rheumatism an enlargement of the left ventricle with enfeeblement seems to be invariable. *It is the first indication of the effect of rheumatism on the* heart, and may be detected when there is no evidence of endocarditis or pericarditis. The left border of the cardiac dulness almost always extends beyond the nipple-line, even in the most subacute attack; usually it reaches one finger-breadth to the left of this line, and it may be even two finger-breadths to the left in a first attack of rheumatism in which there is neither rub nor murmur. The impulse is diffused, and both it and the first sound are weakened. As the attack subsides the dulness tends to return to the normal limit. It may do so completely, but in many instances, especially when a murmur becomes audible the left ventricle remains more or less dilated. A second attack—and to this a rheumatic child is extremely liable—dilates it further, and an accompaniment of endocarditis is only too probable Pericarditis may occur in a first attack, but is usually a later phenomenon. When it occurs it is always accompanied by great enlargement of the heart, causing an extensive increase in cardiac dulness, usually ascribed wholly to pericardial effusion. After repeated rheumatic attacks the child's heart may reach a size which is almost incredible to anyone who has not observed it in the wards and post-mortem room. Clinically, it may extend four finger-breadths to the left of the nipple line and to three finger-breadths in the fourth right intercostal space. In the larger rheumatic hearts there is usually a systolic apex murmur and frequently a presystolic or mid-diastolic also. Evidence of pericardial friction, more or less extensive, is common. Occasionally a diastolic murmur at the base gives proof of aortic regurgitation. It has long been known that in children the cardiac manifestations of rheumatism often are far more pronounced than any other indications of the disease. There may be little or no arthritis, no soreness of throat, no eruption or only a very small patch of erythema, no subcutaneous nodules, no chorea or only slight nervous twitching, yet the cardiac rheumatism may be nothing less than deadly. If all who have to do with children would constantly bear this in mind much suffering would be avoided and many lives would be saved. The slightest suspicion of rheumatism should lead to a most careful examination of the child's heart by palpation and percussion; the practitioner who in this matter relies solely upon auscultation betrays a carelessness which is almost criminal, and shows himself unfit to be entrusted with the vital interests of the child.

In chorea an enlargement of the left ventricle, with or without murmur, is present in the great majority of cases The left border of the dulness almost always extends from a half to one finger-breadth outside the nipple line This seems to be an additional confirmation of the essentially rheumatic nature of nearly all cases of chorea—one extra link in the chain of proof.

The extreme tendency to cardiac disease in rheumatism and in chorea seems to be not merely the result of the poisonous influence of a toxæmia This, no doubt, is a part of the deleterious action produced by rheumatism, and it may perhaps sometimes be the sole cause in a slight attack made a good recovery within one week from the time that I first began to treat him. I see no reason to doubt that the good results in his case, as well as in those of the other four patients, were due to the action of the native remedy, which was the only drug administered.

I have obtained very encouraging results also from the native remedy in cases of bilious remittent fever where the administration of quinine appeared to do more harm than good. Such cases, which are not uncommon in East Africa, begin with general malaise. The patient next complains of frontal headache and of a dull aching pain across the loins; the muscles all over the body feel sore and bruised, as though they had been beaten with a stick; the tongue gets heavily furred; and nausea and bilious vomit declare themselves. The bowels are generally constipated, but in some cases there is bilious diarrhœa. The temperature rises at the commencement of the attack, frequently reaches 105° F., and varies between that and about 101° F. Often there occur clammy sweats which do not appear to have much effect in lowering the temperature. A sour, disagreeable odour, very characteristic of the disease, emanates from the person of the patient and clings to the bedding. The conjunctiva becomes yellowish in hue and there is considerable jaundice of the whole skin. The urine is usually high-coloured, turbid, and offensive in odour. I recollect the case of a European lady in Zanzibar who suffered from such an attack. Although she was literally saturated with quinine—administered by the mouth, per rectum, and hypodermically—yet her temperature remained persistently high for over a month. There was little or no amelioration of the general symptoms, and eventually it was found necessary to send her home.

The *cassia* remedy has proved of much value in several cases of that nature in which I have used it. I may cite the case of a Mission lady who had been suffering for two months when I saw her from bilious remittent fever with nausea and frequent vomiting, headache, and heavily furred tongue. Her temperature, it appeared, had never fallen to normal during all that period and had frequently risen as high as 105° F. She had taken large doses of quinine, sometimes as much as 20 grains daily of the sulphate for many days consecutively. I ordered teaspoonful doses of the liquid extract of the *cassia* root to be taken every four hours. I saw her again after three days; her temperature was then normal, her tongue was quite clean, she had no headache, and she had begun to feel hungry. She told me that from the time when she took the first dose of the medicine she had had no nausea or vomiting, and that she had begun to mend in every way.

Some of the Fathers of the Roman Catholic Mission in East Africa have made trial of the native remedy, both in the form of the decoction and also of the fluid extract with which I supplied them, in the treatment of blackwater fever. They are, unfortunately, only too familiar with that fell disease, which for years past has claimed a heavy toll of victims from amongst the members of the Mission at their various stations on the mainland. The following is an extract from a letter which I received from one of the Fathers, Père O——, as to his experience with the remedy:—

> With pleasure I give you particulars of my experience concerning the efficacy of the native remedy for blackwater fever. ...... I had occasion to try it in the case of one of my *confrères*—a missionary suffering from a violent attack of blackwater fever, as diagnosed by a German doctor of medicine. The valued patient recovered from the attack, thanks to the decoction of the root. Fifteen days afterwards I had a similar experience in the case of a German *non-commissioned officer* who had been ill with blackwater fever for a period of 10 days and who was in the last extremity. Without omitting to administer a good emetic of ipecacuanha I caused him to drink every hour a cupful of the decoction, and 48 hours later the patient, who is to-day on the active list of the colonial army, was out of danger. The hæmoglobinuria had ceased within barely 18 hours from the first administration of the remedy. I have also proved its efficacy against blackwater fever in the case of another of my *confrères* and likewise in the case of a German Captain who is [illegible] active service. I had a like happy result in the case of anoth[illegible] sergeant. As regards its efficacy against the hæmaturi[illegible]e, from which the blacks suffer I have proved it in[illegible] anæmic [illegible] cutaneous [illegible] on ac[illegible] em[illegible] paraly[illegible] German s[illegible] ordinarily simple [illegible] han 30 instances.

Père E——, who has resi[illegible] for over 37 years [illegible]ded in various parts of tropical East Africa [illegible] and who probably has seen more cases of b[illegible]ackwater fever du[illegible]ring that period than any other man now li[illegible]ing, wrote to me as follows:—

> I have had occasion to employ very freq[illegible]uently the native remedy, in the form of a decoc[illegible]tion, in cases of blac[illegible]water fever, and I have had in every instance [illegible]ery good results from [illegible] it. I did not lose one patient of those whom I treated with that re[illegible]medy. ...... Since I received from you the fluid extract I have had occasion to employ it in two cases and each time with the best results. The first case was that of Brother A—— who doubtless has told you how I cured him within a few hours. The second case was this:—some two months ago I arrived at Bagamoyo and there I found Sister M—— *in extremis* as the result of a very bad attack of blackwater fever; the last rites of religion had been administered to her and her death was expected from

from the abuse of quinine; but that it finds its most favourable nidus for development in the system of those persons who have become debilitated by repeated attacks of malaria.

As regards the treatment of blackwater fever it must be confessed that medical science has hitherto been completely baffled. Quinine, in one or other of its forms, is the drug which has been most generally employed in the treatment of the disease in question. Its selection was based upon the belief that blackwater fever was a complication of ordinary malaria, and it was assumed that the drug, being undoubtedly possessed of remedial virtues in connexion with what was supposed to be the primary disease, would yield good results in the complication also The test of practical experiment has demonstrated the unsoundness of such reasoning, and it is now the opinion of most medical men who have had considerable experience of blackwater fever that the exhibition of quinine in cases of that disease aggravates the symptoms and is distinctly harmful. Such is also my own personal opinion. Indeed, it might have been inferred *a priori* that quinine, which acts simply as a parasiticide and not as an antitoxin, would fail to yield good results in hæmoglobinuric fever, since the destruction of the blood corpuscles which takes place in that disease is due, not to the direct action of individual parasites, but to the influence of the toxin present in the system The aggravation of the symptoms produced by the administration of quinine is explained by the discovery made by Professor Koch that the drug in question exerts a toxic influence upon diseased blood corpuscles, which it destroys There is only one legitimate rôle for quinine in connexion with blackwater fever—namely, that of a prophylactic against ordinary malaria. By guarding the system against attacks of that disease it will at the same time guard in great measure against attacks of the more formidable malady also

Various drugs other than quinine have been tried from time to time in the treatment of hæmoglobinuric fever. I may cite, for example, ergot, tannin, and perchloride of iron. No satisfactory results have been obtained from their administration, and, indeed, it is difficult to understand by what process of reasoning the employment of such drugs can be justified. Boric acid also has been tried in the hope that it might prove efficacious by reason of its antiseptic properties, but so far as I know the results of that method of treatment have not been encouraging. In a word, amongst officinal preparations there appear to be none upon which, employed either singly or in combination, any reliance can be placed for the treatment of blackwater fever.

I come now to a consideration of the native remedy for the disease in question. I first heard about it some years ago, during my sojourn in East Africa, from a very intelligent Arab who had travelled much between the coast and the great central lakes, and who in the course of his journeys had seen the remedy used by some of the tribes in the interior, amongst whom blackwater fever would appear to be endemic. The remedy in question consists of a decoction made from the roots of a *cassia* which grows in equatorial East Africa from sea level up to an altitude of some 2000 feet The tree attains a height of from 20 to 30 feet; the inflorescence is bright yellow in colour, and the ripe seed pod is about two and a half feet in length The botanical characteristics of the tree in question have been described and figured by Mr. E. M. Holmes, F L S, curator of the museum of the Pharmaceutical Society of Great Britain, in the *Pharmaceutical Journal* of Nov. 30th, 1901, and of Jan 18th, 1902 Mr. Holmes is of opinion that the tree is a new species and he has named it *Cassia Beareana*. The native method of preparing and administering the decoction is as follows: they chop a portion of the root into pieces, each about one inch in length, and of those pieces they boil about one dozen in a gallon of water for half an hour or so The result is a red-coloured fluid of which the patient suffering from blackwater fever is given to drink, either hot or cold, as often as he feels thirsty. Apparently it is non-poisonous in its action and may be consumed in unlimited quantity. In cases where the patient does not suffer from marked thirst the decoction is administered in doses of about a teacupful every couple of hours The natives employ the same remedy, and they claim for it specific virtues also in the treatment of that simple form of hæmaturia—i e., unaccompanied by febrile symptoms—which is so prevalent amongst the negroes of East Africa. The only portion of the tree, other than the roots, employed medicinally by the natives is the bark, which they powder and apply as a dressing to ulcers, apparently with good results.

I succeeded in procuring a supply of the roots of the tree in question and I sent some of them to Messrs. Christy and Co. of London for the purpose of having made therefrom a preparation which would approximate as closely as possible to the decoction used by the natives. Messrs. Christy and Co. accordingly made for me a fluid extract of the root, by maceration and percolation, with distilled water evaporated at a low temperature, 25 per cent. of alcohol of 90° being added to preserve it. The action of the fluid extract thus prepared would seem to be identical with that of the simple decoction. I have treated five cases of blackwater fever with the native remedy. Of the five patients two were Africans, two were Arabs, and one was a native of Beloochistan. In the case of the two Africans and of one of the Arabs the attack in each instance was of moderate severity and had not long declared itself when I began the treatment. In the case of the other Arab and of the Beloochi the attack in both instances was severe and had declared itself several days before I saw the patients. The negroes assured me that they had neither of them ever had a dose of quinine; that statement was doubtless correct, as they came from the interior and had never been brought into contact with Europeans. Both of the Arabs and the Beloochi had apparently been treated with quinine at various times for attacks of ordinary malaria, but each of them assured me that he had had no quinine for at least two months prior to the attack of blackwater fever All five patients had suffered considerably on and off from attacks of ordinary malaria. The Beloochi, from his account, appeared to have suffered at least once before from blackwater fever, but in the case of the other four patients the attack of that disease for which I treated them would seem to have been the first of that nature from which they had suffered. The two Africans I treated with the decoction of the *cassia* root prepared in the native manner. I gave about a teacupful as a dose every two hours during the first 12 hours, and afterwards a similar quantity every three or four hours. Both patients made a speedy recovery; the temperature fell gradually from 103° F. to nearly normal within 24 hours, and the urine, which had been scanty in quantity and very dark in colour in each case when I first saw the patient, became more abundant and almost clear in colour within the same period. The nausea and bilious vomit which had distressed the patients at first quickly subsided and on the second day they were able to retain a fair quantity of liquid nourishment On the third day the temperature was normal, the urine was almost quite clear, the nausea and vomiting had ceased, and the tongue had begun to clean. Within six days the patient in each case was convalescent, but I continued to administer a dose of the decoction three times daily for a few days after all the symptoms had disappeared. There was no relapse in either of the two cases within a period of two and of two and a half months respectively, during which periods I had an opportunity of seeing the patients from time to time The two Arabs and the Beloochi I treated with the liquid extract. For a dose I gave one fluid drachm well diluted with water every two hours at first, and afterwards at longer intervals Those three patients also made a rapid recovery. The case of the Beloochi was particularly striking. When I first saw the man he had been suffering for three days. He was deeply jaundiced, the tint of his skin being a greenish bronze; he suffered acutely from gastralgia, with nausea and continual vomiting; his urine was scanty and nearly black in colour, and his temperature was over 104° F. In a word, his was a typical case of a severe attack of hæmoglobinuric fever. The administration of the first dose of the fluid extract was followed by an attack of vomiting after an interval of but a very few minutes. I waited for some five minutes and then administered about a teaspoonful of the mixture; this was retained and no vomiting ensued for nearly half an hour. After an interval of 15 minutes from the cessation of the vomiting I gave the patient an ounce of the mixture; this also he retained and he slept for nearly an hour. Again he vomited, and again after an interval of 15 minutes I gave him an ounce of the mixture. The nausea and vomiting gradually diminished, he took and retained a couple of ounces of the mixture every few hours and within 24 hours the nausea and vomiting had practically ceased. As in the case of the other four patients his urine became more abundant and clearer within 24 hours from the first administration of the remedy, his temperature fell steadily, he got a fair amount of sleep after the first 12 hours of treatment, and he was able to retain some nourishment. He measurements of the light was an electrical one, Mr. Leslie Miller, A.M.I.E.E., gave me his skilled assistance, and I am also indebted to him for various suggestions that are embodied in the paper.

At the commencement I recognised the fact that the only way that would decide whether the attempt to improve the apparatus for the light treatment of skin disease was successful or not would be to give it a fairly lengthy trial on patients suffering from that disease. No experiments such as those of Dr. Strebel on cultures of the bacillus prodigiosus inclosed in glass cells with quartz lids would give any certain knowledge of what would happen to other species of bacilli in the human skin, and therefore we felt it would be useless from a medical point of view to bestow extreme care and much time on carrying out quantitative experiments on bacteria. I therefore confined myself to proving that the apparatus hereinafter described gave out the necessary ultra-violet radiation for practical trials in the treatment of lupus in the electrical department of St. Bartholomew's Hospital.

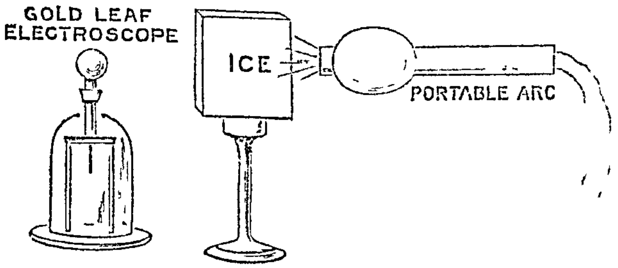
In the first place, it is necessary to regard light used for bactericidal purposes from the mental standpoint of a man born blind. White light is then electrical vibrations or waves in the ether and is merely the octave to which our retina responds in a whole series of ether vibrations. This is not the place to go into the subject of the measurement of wave lengths. It will therefore suffice to point out that when white light is resolved into its component parts of red, green, violet, &c., the wave lengths are as follows: where $\lambda$ = the wave length and $\mu\mu$ the millionth of a millimetre, red to green from 698 $\mu\mu$ to 500 $\mu\mu$; green to blue, 500 $\mu\mu$ to 457 $\mu\mu$; blue to violet, 457 $\mu\mu$ to 392 $\mu\mu$; and ultra-violet, below 392 $\mu\mu$. According to Dr. Strebel the spark of an induction-coil between the following metal points gives waves of which the shortest wave lengths are as stated: aluminium, 185 $\mu\mu$; zinc, 202 $\mu\mu$; cadmium, 214 $\mu\mu$; and carbon, 229 $\mu\mu$. He also says that water 8·5 millimetres thick inclosed between two quartz plates 1·3 millimetres cuts off all lines below 214 $\mu\mu$, but this appears to be rather overstated, probably owing to an almost invisible film of foreign matter on the quartz nearest the arc.

Now, it has been proved by numerous investigators that the bactericidal rays are those that correspond to the blue, violet, and ultra-violet region of the spectrum, and by Dr. Strebel that the shorter waves beyond the violet, called the ultra-violet, will kill bacteria when the visible rays have been altogether shut off. Up to the present time, however, no one has proved what wave length is the most effective, and this is a point much needing investigation. On the one hand, we have the fact that Professor Finsen by means of his earlier form of lamp through which few ultra-violet rays could pass, undoubtedly cured lupus, although slowly; on the other hand, we have the investigations of Dr. Strebel who destroyed the cultures of the bacillus prodigiosus under quartz by means of the ultra-violet rays alone. Even when concentrated by means of lenses sunlight has been found by Professor Finsen not to be so effective as arc light. This is probably due to the fact that the extreme ultra-violet rays of sunlight are absorbed in our atmosphere, and it is due to their presence in the arc that the latter is superior to sunlight.

P. Lenard[1] has shown that the extreme ultra-violet rays generated by an electric arc are absorbed by a layer of air two centimetres in thickness, and he is of opinion that these rays are contained in sunlight but only in the higher regions of the atmosphere. Spectroscopic observations showed the wave length of these rays to be shorter than those hitherto mapped, ranging as they do from 160 $\mu\mu$ to 190 $\mu\mu$. It is easy to satisfy oneself of the absorption of the violet end of the spectrum by the spectroscopic examination of the sun when on the meridian and when near the horizon. It is only necessary to take photographs of the spectrum at these times to see the great amount of absorption which takes place in the violet and ultra-violet regions of the spectrum when the sun is on the horizon. Of course, the light from the setting sun has a much longer column of air to pass through than when on the meridian.

This paper is concerned merely with proving that a certain source of light gives out an abundance of extreme ultra-violet, with a fair proportion of rays of lower refrangibility. To prove this three methods were available: (1) by photography (chemical action); (2) by changing the short waves into longer by letting them fall on to some substance that will become fluorescent and thus render them visible; and (3) by an electrical method—viz., letting the rays impinge on a piece of bright metal (zinc or aluminium) connected with the leaves of a gold-leaf electroscope charged with negative electricity. By photography it was easy to prove that the source of light gave off rays far beyond the visible violet of the spectrum, but it was not at all easy to compare the negatives so as to judge the intensity of the source of light. For instance, one candle will give a spectrum as long as 20 candles, but some easy way of knowing that the source was 20 times as powerful in the second case as in the first was wanted and this involved equal exposures and the same development. In addition to this dry plates are not equally sensitive to waves of all wave lengths and not sensitive at all to very short waves, simply because, as proved later, they will not penetrate the gelatin of the films. By means of a spectroscope fitted with a quartz prism and quartz lenses a number of photographs of the spectrum were taken, but finally photography was given up and the spectrum observed after the light had passed through the quartz prism and lenses on to an ordinary platino-barium screen and on papers which had received washes of solutions of esculine, fluoresceine, and sulphate of quinine. This method is much quicker but not altogether satisfactory, as the visibility of the ultra-violet portion of the spectrum depends largely on the successful darkening of the room. Another and fatal objection to this method of observation was this—the total thickness of the quartz train (lenses and prisms) was upwards of an inch, and this must offer a considerable obstruction to short waves. Finally, the electrical method mentioned above was adopted, with the view not only of measuring the power of the very short rays (about 200 $\mu\mu$) that alone affected the gold leaves, but because it was found that these rays always seemed to bear the same proportion to those that caused fluorescence, and the latter could only be roughly measured by the eye. Waves of different length have different degrees of penetration for the same substance, and a given wave does not penetrate various materials equally well. In the general way the shorter the wave length the less the penetration. Ultra-violet rays of short wave length reach the tops of mountains but not the valleys, and still less penetrate glass windows. As the micro-organisms of lupus (tubercle bacilli) are mostly situated in the deeper layers of the skin it is absolutely necessary that the rays should have sufficient penetration to reach them. If a small antrum lamp be placed in the mouth in a dark room the light penetrates the skin and bone easily enough, but these rays would not kill the bacilli as they are mostly those towards the red end of the spectrum. The wave length is, however, so easily lengthened or shortened by impinging on various bodies that it would not be wise to dogmatise on this point. A ready means of testing the penetrating power of the extreme ultra-violet rays of the metal arc was wanted, and this was found in the gold leaf electroscope. The action of this instrument depends on a property possessed by the waves, chiefly those of shorter wave length than about 200 $\mu\mu$, to render gases through which they pass conductive. If the rays are directed against the ball or plate of a gold-leaf electroscope charged negatively the leaves fall together with a rapidity depending on the power of the light falling on them. The general arrangement is shown in the illustration (Fig. 1).

Fig. 1.



The leaves are charged till they diverge a certain distance, then the rays of the lamp are directed on to the ball or plate and the time taken that elapses before the leaves fall together. In this way the following facts were demonstrated:—1. Two pieces of quartz about 2·2 millimetres thick and separated from one another by a space of 10 millimetres, stopped 60 per cent.

---

[1] Annalen der Physik, March, 1900.

hour to hour. I immediately gave her some of the fluid extract, 150 drops in two tumblers of water, which she drank in sips; it was with much difficulty that she could swallow even a little water. After some hours the attack was checked and the urine became clear. She remained for some time very weak as the result of the attack, but she has completely recovered and is now doing her work like the other Sisters.

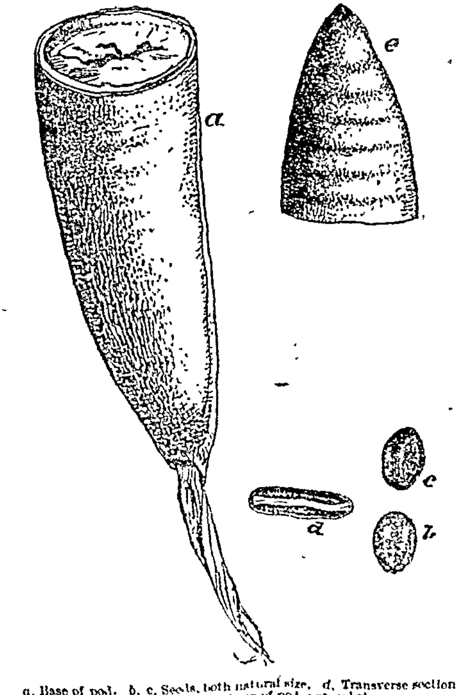
Such, then, is a *résumé* of the results obtained by the Mission Fathers and by myself from the employment of the native remedy in question Those results appear to me to be very encouraging, so far as they go, and I venture, therefore, to propose to my colleagues in the medical profession that they also shall make trial of the *cassia* preparation, and that they shall record their experience of its action, so that the question of the therapeutic value of the preparation may be determined. It is not an exaggeration to say that the discovery of a reliable remedy for blackwater fever is a matter of vital importance for the welfare of our colonies in tropical Africa.

I have sent a supply of the root of *Cassia Beareana* to Messrs. Christy and Co of 4, Old Swan-lane, Upper Thames-street, E.C., who will furnish gratuitously samples of the fluid extract of same to medical men and others desirous of testing the remedy.

### NOTE BY E M HOLMES, F.L.S.

The plant affording the root used by Dr. O'Sullivan-Beare as a remedy for blackwater fever is a small tree, from 20 to 30 feet high, having a trunk about six inches in diameter when fully grown and the habit or form of an apple tree. It belongs to a small group of trees in the genus *Cassia* (Nat Ord. *Leguminosæ*) of which *Cassia fistula* is the type. The trees of this group have long, hard, cylindrical or compressed pods, attaining from one to two feet in length, and divided internally into numerous cells by transverse partitions, each cell containing a seed transversely placed. The leaves have numerous pairs of leaflets about one inch or more in length. The species differ chiefly in the colour and markings of the flowers, the persistent or fugacious character of the bracts, and the shape of the pods and seeds, and by the presence or absence of a swelling in the middle of the longest stamens. The particular species which yields the blackwater fever remedy is very closely related to *Cassia abbreviata*, Oliv., to which, until I had seen the pod and seeds, I supposed it to belong; but although it has yellow flowers beautifully reticulated with reddish-brown veins and persistent bracts like that species, it differs from it in having a compressed, smooth, not hairy pod and oval seeds, and in having the swelling in the middle of the long stamens very pronounced. As it differs in essential characters from any species hitherto described I have named it in honour of its discoverer, *Cassia Beareana*, n. sp, and have given the following description of it in the *Pharmaceutical Journal*, Jan 18th, 1902, p. 42

FIG. 3.



a, Base of pod. b, c, Seeds, both natural size. d, Transverse section of seed enlarged. e, Apex of pod, natural size.

*Cassia Beareana, n. sp.*—A small tree attaining 20 to 30 feet, the young leaves not seen, but the inflorescence is shortly pubescent, especially on the rachis. The leaves are about eight to 10 inches long, and the leaflets in eight to 10 pairs, elliptical, obtuse, rounded, or very broadly cuneate at the base, glabrous, with reticulate venation. The leaflets are one and a quarter to one and a half inches long, and three-fifths to nearly an inch wide in the centre, petiolules about one line long, slightly rugose, the common petiole without glands. Racemes on (terminal and (?)) lateral shoots, rather short and subcorymbose, the rachis about three inches long, shortly pubescent, with persistent recurved bracts and bractlets, about one quarter to one-third of an inch long, linear, acuminate, and minutely glandular pubescent. Pedicels ascending, straight, slender, furrowed, faintly pubescent, or nearly glabrous, two and a half inches long. Petals obovate oblong, scarcely tapering to the base, three-fifths to three-quarters of an inch long, canary yellow, beautifully veined with dark red or chestnut veins. The longer stamens exceed the petals; the filaments are distinctly dilated near the middle. The young ovary is covered with appressed whitish hairs. Legume about 30 inches long, one inch broad, and half an inch thick, compressed, with the sutures not at all prominent, glabrous, or not visibly hairy, with the dissepiments showing on the surface as transverse lines about quarter of an inch apart. The seeds are blackish, brown, oval, about seven-sixteenths of an inch in length, and five sixteenths of an inch in width, and nearly one eighth of an inch in thickness, with a central longitudinal linear depression, and do not appear to be surrounded with pulp.

# ON THE ULTRA-VIOLET LIGHT FROM A RAPID OSCILLATION HIGH-TENSION ARC, FOR THE TREATMENT OF SKIN DISEASES.

By HUGH WALSHAM, M.A., M.D CANTAB.,
F.R C.P. LOND.,
ASSISTANT MEDICAL OFFICER IN THE ELECTRICAL DEPARTMENT,
ST. BARTHOLOMEW'S HOSPITAL; ASSISTANT PHYSICIAN,
CHEST HOSPITAL, VICTORIA PARK.

IT is now established quite beyond question that sunlight and the light given off by the electric arc have the power of retarding the growth, or even of killing outright, various kinds of micro-organisms exposed to their influence. The credit of first having pointed out this action of light on bacteria undoubtedly belongs to Downes and Blunt who, as long ago as 1878, communicated a paper to the Royal Society on the *Influence of Light on Protoplasm*. The subject appears to have been quite lost sight of until 1892, when Professor Marshall Ward communicated a paper, also to the Royal Society, entitled, "Experiments on the Action of Light on the Bacillus Anthracis." Professor Ward says: "The results are as startling as they are important, for if the explanation given of the phenomena observed in the following experiments turns out to be the correct one we stand face to face with the fact that by far the most potent factor in the purification of air and rivers of bacteria is sunlight." Professor Ward treated the subject from a purely scientific point of view, and probably had no idea of the importance of his experiments in relation to the treatment of disease. The credit of having applied the knowledge of the bactericidal action of light therapeutically belongs without doubt to Professor Finsen He made use of both sunlight and the electric arc, but found the latter more efficacious. The next important communication on the subject is from the pen of Dr. Strebel of Munich to which reference will be made later.

Before giving any account of the experiments which form the subject of this paper I must explain that as soon as it became apparent that the best method of making

Angabe einer Methode zur besseren Ausnutzung der Bakteriziden Kraft des Voltabogenlichtes, von Dr. H. Strebel, in Munchen, Deutsche Medicinische Wochenschrift, No. 5 und No. 6, S. 69. und 86, 1901.

# TWO CASES OF UTERINE CANCER SUCCESSFULLY TREATED WITH CANCROIN.

BY PROFESSOR ALBERT ADAMKIEWICZ.

(*Translated for* THE LANCET.)

NOT long ago I published[1] a case of uterine cancer which had been treated by my method with cancroin and had been cured of very severe symptoms of the disease. The change for the better which speedily followed the use of cancroin and the complete recovery of the patient from a condition of terrible suffering—a recovery coincident with the prolonged administration of the remedy—must remove any doubt as to the connexion between the progress of the case and the effect of my treatment.

In June, 1900, this patient suffered from cancer which filled almost the whole of the true pelvis (*nahezu das ganze kleine Becken entfullenden*); in May, 1901, she was freed from it by injections of cancroin, and in the beginning of October, 1901, she called on me to thank me not only for her recovery but for its permanence. In June, 1900, the case was given up as hopeless by an eminent surgeon, but the excellent health which the patient enjoyed in October, 1901, was conclusively proved by the fact that a medical man who called on her found her engaged in scrubbing the floor in the house where she lived. This condition of the patient is a testimony to the efficacy of my method, and it also shows that the continued observation of a patient restored to health by cancroin is a public duty, in order that the merits of an excellent method of treating cancer, now at last discovered after thousands of years, may not, to the detriment of suffering humanity, be nullified by inadequate knowledge.

It is in all cases necessary to make certain beforehand of the presence of the conditions which must be combined in order that the success of my method of treating cancer may be assured; the frequency with which this occurs fills me with the hope that by systematic and at the same time strictly correct application of my method such cases will soon be no longer rarities but will be the rule, and I am encouraged in this by the fact that in the case now to be described improvement and recovery were brought about in a surprisingly short time by careful utilisation of all the experience that had been gained with my system of treatment.

The following description of the case was placed at my disposal by the medical man in attendance on the patient and will speak for itself.

## PREVIOUS HISTORY OF THE CASE.

"The patient, a married woman, 36 years of age, residing in Vienna, fell ill with severe hæmorrhage in February, 1901. Several gynæcological specialists who were consulted agreed in diagnosing cancer of the cervix uteri. Hofrath Dr. Chrobak raised the question of total extirpation of the affected uterus, but this was not carried out, only the cervix being scraped in the Sanatorium Furth on March 13th. Microscopical examination showed the disease to be cancer. Immediately after the operation Hofrath Chrobak declared that the case was one of those in which operation offered not the slightest prospect of success, and he gave a relative of the patient a description of the well-known stages through which the disease would pass and of the distressing manner in which it usually terminated, winding up his observations with the remark that it would be better for the patient if she did not awaken from the anæsthetic. This dismal picture of what was in store for the sufferer very soon received a melancholy confirmation, for the most dreadful pains were the immediate sequel of the operation and continued as a permanent symptom, alternating with hæmorrhages. The disease became worse and worse, and the patient was soon unable either to leave her bed, to sit up in bed, or to lie on her side Even her power of taking food suffered, for she vomited what she ate. Her bowels never acted without the help of medicine, defecation was extremely painful, and her urine had to be drawn off with a catheter. Repeated consultations with Hofrath Chrobak and Dr Herzfeld led to no result. Both of them pronounced the disease to be inoperable carcinoma; they said that the case was hopeless, and they could only sympathise with the patient and with me the medical attendant. Examination of the patient showed that in the position of the portio vaginalis there was now a dense-walled, easily bleeding, cup-shaped excavation, and above the sphincter and on the anterior wall of the rectum a tumour could be felt, very painful when touched, and of the size and shape of a pear. The abdomen was extraordinarily painful and palpation through its walls was impossible.

I was in despair and unable to offer any suggestion. In this extremity I applied to Professor Adamkiewicz in the middle of June. After he had seen the patient and examined her he pronounced the case to be too far advanced and declined to recommend any treatment, but on my earnest entreaty he reconsidered his decision. He gave the first injections of cancroin himself, prescribed the manner in which they were to be continued, and then left me to give them in accordance with a system adapted to their action and effects.

This treatment was a brilliant success. The hæmorrhage and abdominal pains disappeared promptly. On the second day of the injections the patient sat up in bed free from pain and quite at ease, and took her breakfast with relish. She soon had an excellent appetite and all kinds of food agreed with her. Fæces and urine were passed without pain; her strength increased; her condition improved manifestly; and a feeling of tranquillity and of confidence in her recovery did the rest. Repeated local examinations made at a subsequent period showed that the tumour which had formed above the sphincter and on the anterior wall of the rectum had entirely disappeared, and its former position was no longer indicated even by a sensation of resistance. The excavation in the cervix had become smaller and was smooth-walled. The patient, who four weeks previously could not move herself in bed, had now left her bed, walked freely about the house, and intended one of these days to go into the country quite cured.

I have to express my heartfelt thanks to Professor Adamkiewicz for saving my patient who had been given up by all the medical men previously called in consultation.

DR. KARL STOCK.

Vienna, VII. Burggasse 70, July 31st, 1901."

To the foregoing narrative, written by the medical man in attendance on the patient, I have to add what follows.

When I saw the patient for the first time in the middle of June, 1901, she had an earthy complexion and lay in bed shivering, lamenting, and dreading every movement. There was a cooling application on her abdomen which was distended, painful, and unable to bear the slightest touch. In the end of July—namely, after only six weeks' treatment with cancroin—I found her handsomely dressed, walking freely about the house, conversing cheerfully, free from pain, full of happiness and enjoyment of life. She was not only saved from impending death, she was restored to health. In the meantime I directed as a measure of precaution that the injections should be continued in a modified form in the country place to which she was going for the completion of her convalescence, but the carrying out of these orders was interrupted by an incident which was no less remarkable than unexpected, for certain females in whose care she was placed induced her to make a will in their favour and then persuaded her that it would be better for her not to allow the injections to be continued.

In the middle of August she complained of dysuria and tenesmus, and examination showed the existence of a doughy and very painful swelling of the uterus. It was immediately obvious to me that colonies of cancer coccidia, survivals from the previous illness, had subsequently attained further development and that the inflammation of the uterus must be due to them. I immediately gave most positive directions that the injections of cancroin should be resumed, but for the reasons already mentioned these orders were disregarded, and so the metritis had time to assume dimensions which threatened the patient's life. The pain which she suffered caused her to scream and almost drove her out of her mind; when she had an attack of it she could not stand or lie down or sit, and of the rays that affected the instrument. 2. When the space between the two discs was filled with water, from 10 to 15 per cent. of the remainder were stopped. 3. A film of transparent gelatin 0·04 millimetre thick stopped the whole of the rays. (This is in practical agreement with Dr. Strebel's result, that gelatin 0·5 millimetre thick stopped all rays below 257 $\mu\mu$.) 4. A block of ice six inches thick offered scarcely any more obstruction than the same column of air. 5. When the arc was formed between iron points the effect was double that due to zinc. The iron arc, however, was visibly the larger of the two. 6. The least film of iron oxide on the surface of the quartz stopped the effect almost entirely. Unfortunately, iron oxide is given off rather freely, and on this account it is not advisable to work with the quartz too close to the arc. On the whole iron seemed the most practical of various metals tried. According to some particulars recently published[2] of Dr. Bang's new arc lamp with water-cooled carbons, after carbon he prefers silver and some kinds of iron. The bactericidal power of this lamp is said to be 19 times that of an ordinary arc. In a more recent account of this lamp Dr. Bang[3] claims 60 times the efficiency.

---

[1] Berliner Klinische Wochenschrift, 1901 No. 23.

The extraordinary transparency of ice to the rays seems a fact of much importance. Professor Finsen has proved that blood offers the chief obstruction to short waves. If therefore the part to be treated can be rendered anæmic by pressure, the ultra-violet rays have a greater chance of exerting their destructive action on the bacilli. Hitherto pressure has been the only means resorted to, but there seems to be no reason why cold should not be employed in addition. Since the heat from the high oscillation arc is at the most one-tenth that of an ordinary 10-ampère arc, a disc of ice one inch in thickness in front of the arc will last long enough for one exposure. Ice thus fulfils the double object of rendering the part anæmic and allowing sufficient compression to be applied.

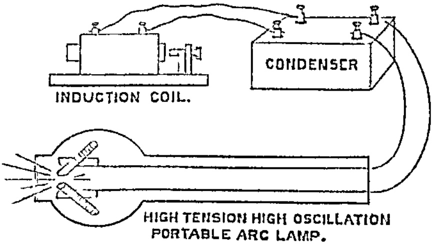
A few comparisons were made of the action of one of the ordinary 10-ampère lupus arc lamps now used, with the quick oscillation arc. In the lupus lamp the usual carbons were employed. The metal shield was fitted with a compressor consisting of two discs of quartz together equal to about five millimetres in thickness, with a layer of water between of about 13 millimetres. The gold-leaf electroscope was not appreciably affected and the fluorescent effect was only just visible. When the naked arc without any quartz or water was used there was just about the same effect on the gold leaves as with the quick oscillation arc, also naked. The fluorescent effect appeared to be about the same, but the eye cannot be depended upon when the general illumination is quite different.

Another comparison was made between the effects of a step-up transformer worked from the street alternating main and a 12-inch induction coil worked from eight cells of an accumulator battery (16 volts). The pressure of the transformer had been adjusted so that the arc formed was about that suitable for treatment. Speaking generally under these conditions no difference could be perceived. This result is surprising, but the number of oscillations of the current influences the light-giving powers of the arc to an extent that cannot be predicted. With the coil, at most 16 volts and five ampères = 90 watts were taken from the accumulators, most of which energy was wasted in the coil and condenser, while an ordinary arc takes 450 watts in the arc alone without the waste in any resistance that may be employed.

Cases of lupus vulgaris and lupus erythematosus have been under treatment in the electrical department by this source of light. Cases of the former variety of the disease make more progress than the latter. The time of exposure has been from 10 to 15 minutes. And here I would point out the importance of compression. Cases in which this can be efficiently applied (as, for example, lupus on the end of the nose) improve much quicker than cases in which the compression is more difficult. At the present time it is somewhat hard to tell whether a given case of lupus will do better with the x rays or the ultra-violet rays. Many observers appear to regard the treatment by x rays and by light as something quite different. When we consider, however, in how many ways ultra-violet light and x rays are alike the distinction between the two almost vanishes. Both act chemically, both produce fluorescence in bodies, both discharge the gold-leaf electroscope. The action on the skin is, however, somewhat different, although they are both capable of producing dermatitis and pigmentation. In the case of the light treatment dermatitis supervenes after some hours; whereas with x rays it may require even weeks to produce it. Again, the dermatitis produced by the ultra-violet rays soon resolves, but it is well known that the x ray form may take weeks or even months to heal. It is true that x rays have more penetration, but in passing through a body they generate secondary rays which have a great analogy to ultra-violet rays. It is probable that secondary rays are Roentgen rays very slightly penetrative and possibly intermediate between the rays from a soft tube and extreme ultra-violet rays.[4] There is, according to current belief, a great difference in their action on bacteria, the x rays being said to stimulate their growth while the violet and ultra-violet rays are known to kill. In fact, we may say that the only absolutely sure ground on which we may build is that the ultra-violet rays will kill bacteria outside the body. Other observers are treating cases of lupus with the static breeze and the Tesla condensing electrode. The Tesla electrodes have been used with success in the department, and it appears to me in all these various methods of treatment that the only one point they possess in common is the ultra-violet ray.

The illustration (Fig. 2) will sufficiently show the general form of the lamp as used in treatment in the electric department of the hospital. When used from the street mains great care is necessary to see that there is no defect in the insulation, otherwise a severe shock may result. When worked from an induction coil ordinary precautions only are required. But in all cases it is necessary to shield the eyes from the arc or severe conjunctivitis may result. The apparatus is about a foot long and the tube is one and a half inches in diameter. When the end is not closed by a disc either of quartz or ice the arc makes a considerable noise. It is of course quite easy for the patient to press the end against the skin when the patch of lupus is conveniently situated.

FIG. 2.



It has already been shown that all materials used as compressors, or heat arrestors, unfortunately obstruct many of the bactericidal rays. A simple plated grid as a compressor has therefore been tried. This allows the naked arc to be used for a limited time at a distance of one and a half inches from the skin. Ice, however, has so many advantages both from a theoretical and practical point of view that it has been adopted in nearly all cases. These advantages are so important that it may be well to enumerate them: (1) it is hard enough to cause efficient pressure; (2) it adds to this effect by increasing the anæmia by cold; (3) by its transparency it allows the individual lupus nodules to be clearly seen; and (4) it is transparent to the violet and ultra-violet rays of the spectrum and opaque to the red and infra-red.

So far as I can see from about two months' treatment of lupus patients the curative action of the light given off by this apparatus is satisfactory.

time prior and up to the time of the shooting. The district attorney, also within a few hours after the crime was committed, proceeded to put the prisoner under the observation of local experts in mental disease—namely, Dr. Joseph Fowler (police surgeon), Dr. Floyd S. Crego, and Dr. James W. Putnam. These physicians had free access to him down to and during the trial, covering a period of nearly three weeks, during which they examined him repeatedly and made a careful study of his case with reference to his mental condition. The district attorney also permitted the experts on either side to confer together freely, and allowed those for the defence to have free access to all facts and information relative to the case in his possession—a proceeding which in effect was equivalent to the appointment of a commission of five experts, three for the prosecution and two for the defence, to determine the prisoner's mental condition. This course on the part of the district attorney marks a new departure in the methods of getting expert evidence in criminal trials where the question of mental responsibility is involved which is to be highly commended as a practical measure tending to eliminate much superfluous testimony and at the same time to minimise the danger of contradictory expert opinions.

In view of the great importance of the case it is regrettable that no experts were called to testify on the trial as to the prisoner's mental condition in order that it might appear on the record of the trial that his mental state was inquired into and determined by competent authority. Had the experts on either side been given the opportunity of thus stating officially their unanimous conclusion, together with the grounds on which it was based and the methods by which it was reached, it would have left in the public mind no room for reasonable doubt as to its absolute correctness, and that it had been arrived at only by the rules of professional conduct governing the examination of such cases.

The attorneys assigned by the court to the defendant, at the request of the Bar Association of Erie County, were ex-judges Loran L Lewis and Robert C. Titus, both prominent lawyers and highly respected citizens of Buffalo. For obvious reasons these gentlemen were reluctant to undertake what they regarded as a most distasteful task, and consented to do so only from a high sense of duty to the public, at the urgent solicitation of the President—the Hon. Adelbert Moot—and other prominent members of the Bar Association, on Saturday, Sept. 21st, preceding the trial, which began on Monday, the 23rd.

Respecting the defence, it appears that substantially no preparation was made beyond a fruitless effort of counsel to confer with the prisoner and the examinations made of him at their request by Dr. Hurd and the writer with reference to his mental condition, and a verbal statement by them to counsel of their conclusion that he was not insane. It also appears that no plea was entered by the attorneys for the defence, but Czolgosz, speaking for the first time in court, entered a plea of "Guilty" to the indictment, which plea the court promptly rejected and directed that one of "Not guilty" be entered on the record for the defendant.

Each juror on qualifying said, in answer to the usual question, that he had formed an opinion as to the guilt of the prisoner, but that his opinion could be removed by reasonable evidence tending to show that the defendant was innocent. And yet, to one accustomed to being in court and observing jurors when qualifying, it was difficult to avoid the impression that each of the jurors in this case held a mental reservation to convict the prisoner. Had Czolgosz been on trial for the murder of a common citizen instead of the President it is safe to say that not one of the jury as completed would have been accepted by the defence, and instead of getting a jury in approximately one and a half hours, that feature of the trial alone would probably have occupied several days.

Having in view the nature and importance of the case, the fact that no testimony was offered on the defendant's behalf and that practically no defence was made, beyond a perfunctory examination of jurors and a mild cross-examination of some of the people's witnesses which was limited to efforts to elicit information respecting the President's condition during his illness and of his body after death, and a summing-up by one of the counsel—Judge Lewis—which consisted mainly of an apology for appearing as counsel for the defendant and a touching eulogy of his distinguished victim, render the case in this respect a unique one in the annals of criminal jurisprudence.

The jury retired for deliberation at about 4 P.M. and returned in less than half an hour with a verdict of "Guilty of murder in the first degree." Czolgosz heard the verdict of the jury standing and without appreciable display of emotion. Several of the jurors were reported to have said after the trial that the jury was in favour of conviction unanimously from the first and could have rendered a verdict without leaving their seats, but deemed it best to make a pretence of deliberation "for appearance' sake." Czolgosz was remanded to gaol for two days and on Thursday, Sept. 26th, he was sentenced to be executed by electricity at Auburn Prison in the week beginning Oct. 28th, 1901.

When Czolgosz returned to his cell after his conviction he ate a hearty supper and soon thereafter went to bed and slept continuously till midnight, when the guard was changed, when he awoke for a few minutes and then slept again until 6 A.M., when he arose and had a short walk in the cell corridor, after which he made a careful toilet and at 7.30 A.M. partook of a hearty breakfast. He talked freely, as usual, on ordinary topics, but maintained his usual silence respecting his crime and would not talk of the trial or the verdict. On Thursday, Sept. 26th, he was removed from the Buffalo gaol to the State Prison at Auburn, New York, where he was confined in a "death cell" until his execution took place.

### THE EXECUTION.

Czolgosz was executed by electricity on the morning of Oct. 29th, 1901. The official witnesses, consisting of the Superintendent of State Prisons and other prominent New York State officials, several physicians, three representatives of the respective press associations, Mr. Spitzka and others, and the official physicians—Dr. John Gerin, prison physician, and myself—having been assembled in the execution-room and having received the usual admonition from the warden as to maintenance of order during the execution, the prisoner was conducted to the room a few minutes after 7 A.M. Every precaution was taken by the warden, who had immediate charge of the execution, to minimise the opportunity for notoriety or sensationalism on the part of the prisoner as well as to insure that his taking off should be effected in an orderly and dignified manner.

As Czolgosz entered the room he appeared calm and self-possessed, his head was erect and his face bore an expression of defiant determination. The guards, one on either side, quietly and quickly guided him to the fatal chair, the binding straps were rapidly adjusted to his arms, legs, and body, and the head and leg electrodes were quickly placed *in situ* and connected with the wire which was to transmit the lethal current through his body. These preliminaries occupied about one minute. Czolgosz offered no resistance whatever, but during the preparations addressed himself to the witnesses in a clear distinct voice in the following significant language: "I killed the President because he was the enemy of the good people—the good working people. I am not sorry for my crime. I am sorry I could not see my father." At this moment, everything being in readiness, the warden signalled the official electrician in charge of the switch, who immediately turned the lever which closed the circuit and shot the deadly current through the criminal's body, which was instantly thrown into a state of tonic spasm involving apparently every fibre of the entire muscular system At the same time consciousness, sensation, and motion were apparently absolutely abolished. Two electrical contacts were made, occupying in all one minute and five seconds. In the first contact the electro-motive pressure was maintained at 1800 volts for seven seconds, then reduced to 300 volts for 23 seconds, increased to 1800 volts for four seconds, and again reduced to 300 volts for 26 seconds—one minute in all—when the contact was broken. The second contact, which was made at the instance of the writer as a precautionary measure, but which was probably unnecessary, was maintained at 1800 volts for five seconds. That conscious life was absolutely destroyed the instant the first contact was made was conceded by all of the medical witnesses present; also that organic life was abolished within a few seconds thereafter. Czolgosz was pronounced dead by the attending physicians and several of the other physicians present, after personal examination, in four minutes from the time he entered the room; one minute of this period, as already stated, was occupied in the preliminary preparations, one minute and five seconds in the electrical contacts, and the remainder of the time in examinations by the physicians to determine the fact of death. The physicians present at the execution and at the necropsy the only position which was at all supportable for her was when she leaned over the back of a chair and remained hanging on it in a half-upright attitude for hours at a time, occasionally for five or six hours By good fortune for the patient there was a member of her family who was strong enough to break up the conspiracy which had been formed against her life and my treatment, and the moment that the injections of cancroin were resumed the metritis gave way as if at the word of command and the patient began to recover her health. The tenesmus and dysuria vanished. The uterus, the fundus of which could not on its upper side be reached from the rectum, was once more able to be palpated, and in the beginning of October—i e , after hardly four weeks of the resumed treatment with cancroin—it was again changed to a small, hard, uneven, globular mass, easily defined with the finger and no longer painful. Since that time the patient has had no pains ; she can move about quite well, can sit and lie down, and can empty her bladder and rectum without discomfort Painful contractions of the uterus and painful micturition attended by cramps are occasionally felt, when the remnants of the cancer devitalised by the cancroin recover themselves ; but the intervals between these attacks become longer as time goes on. When the attack of cramp is over not the slightest sign of ill-health, either subjective or objective, is recognisable in the patient She is therefore to be regarded not only as being in good health at the present time but as having been on two occasions saved by cancroin.

Vienna.

# THE TRIAL, EXECUTION, NECROPSY, AND MENTAL STATUS OF LEON F. CZOLGOSZ,

ALIAS FRED NIEMAN, THE ASSASSIN OF PRESIDENT McKINLEY.

BY CARLOS F. MACDONALD, A.M., M.D.,
PROFESSOR OF MENTAL DISEASES AND MEDICAL JURISPRUDENCE IN THE UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; EX-PRESIDENT OF THE NEW YORK STATE COMMISSION IN LUNACY.

*With a Report of the Post-mortem Examination,*

BY E A. SPITZKA,
OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THE terrible shock which the assassination of President McKinley by Leon F. Czolgosz at Buffalo, New York, on Sept. 6th, 1901, imparted to the entire civilised world, and which naturally engendered in the public mind a mingled feeling of horror, vindictiveness, and revenge—a feeling which was exceeded only by the profound sense of sorrow and depression which took possession of the people when a few days later it was realised that, despite the highest efforts of surgical and medical skill, a fatal result to the distinguished victim was inevitable—naturally suggested, both to the lay and to the medico-legal mind, the need of inquiry as to the mental status and responsibility of the perpetrator of so repulsive and atrocious an act. Moreover, there are many persons who are disposed to hold that the enormity of such a crime is in itself sufficient evidence to warrant the opinion of the existence of insanity, merely because it seems to them inconsistent with the principles of ordinary rational conduct, even though aside from the act itself there be nothing in the entire life and conduct of the individual that is suggestive of mental disease On the other hand, there are many who, in view of the magnitude of the crime, would oppose the granting of exemption from the ordinary consequences of capital offences, even though the offender were a raving maniac. Suffice it to say that the position taken by such persons in either case is untenable and would be an untrustworthy test of responsibility as regards the ends of justice, whether viewed from a legal or a medical standpoint. It need scarcely be said that the question as to whether or not a certain act is the offspring of mental disease cannot always with safety be determined by the act itself but must be determined by all the attendant circumstances leading up to, and surrounding, the act. "An act of violence," says Ray, "must not be attributed to insanity merely because to a person of high culture and correct morals it seems inexplicable on the ordinary principles of human conduct."

According to the Code of Criminal Procedure of the State of New York, Section 21, the legal test of mental unsoundness, as applied to criminal cases, is based on the assumption that insanity is a question of law to be determined by the court, and that the question of responsibility in mental disease hinges upon a knowledge of right and wrong as to the particular act at the time it was committed ; whereas medical science holds that insanity, in its relation to crime, is always a question of fact to be determined like any other fact in evidence, aided, of course, in such case by the interpretation of expert opinion and evidence, and that whenever its presence can be so determined the accused should be absolved from responsibility, irrespectively of the form or degree of his mental disease or of the nature of the act committed. "All that medical science has to do in any such case," says Dr. John P. Gray, "is to say whether the deed springs from disease or not. If it does not the man is responsible, however ghastly, seemingly purposeless, or vindictive the act may be" In other words, medical science holds that the whole question of responsibility should rest upon the presence or absence of mental disease, and not upon a knowledge of right and wrong as regards the nature and consequences of the act in question, and that that which in fact is a condition of mental disease cannot in law be a condition of mental health The question to be determined then, in the case of Czolgosz from the legal standpoint, as embodied in the Code of Criminal Procedure of the State of New York, was : When he shot the President did he know the nature and quality of the act he was doing and that the act was wrong? If *this question could* be determined in the affirmative, then he was responsible under the law and punishable for the offence which he committed, even though he was medically insane, so to speak. On the other hand, the question to be determined from the standpoint of medical science was : Was Czolgosz at the time he committed the act a victim of mental disease or mental unsoundness? If so, according to the dictum of medical science, he was not responsible and hence not puni*shable for the act which he committed. These* are the sole questions upon which the guilt or innocence of the accused must rest, whether in the eyes of the law or in the judgment of medical science, and it follows logically that if he were guilty of crime owing to the absence of mental disease he was equally guilty within the intent and meaning of the statute. Such being the case the subject of the responsibility of the accused resolves itself into a question of health or *disease—sanity or insanity. Hence* the application of the legal test may be dismissed from further consideration here, and we may proceed to consider the question of his responsibility from a medical point of view.

## THE TRIAL.

The trial of Czolgosz, which took place in the city of Buffalo, New York, on Sept 23rd and 24th, 1901, the Hon. Truman C. White being the presiding justice, was neither attended by delay "nor harassed by the trivial technicalities of the law." The "machinery of justice" moved so smoothly and so rapidly that the jury was procured, the case tried, and a verdict of "Guilty" rendered within a period of two court days with sessions from 10 to 12 o'clock in the forenoons and from 2 to 4 o'clock in the afternoons, the time actually occupied being eight and a half hours in all The proceedings were marked by no melodramatic or sensational episodes or unseemly wrangle among counsel ; while the fact that, under the extraordinary circumstances, the trial was not anticipated or interrupted by any riotous demonstration against the prisoner—any attempt at mob or lynch law—when he appeared in public affords striking proof of the respect for law and order which prevails in the community where the trial was held Czolgosz was brought into court closely guarded by a double cordon of police and handcuffed to an officer on either side He was neatly dressed and cleanly in appearance, his face being clean shaven and his hair neatly combed

The preparation and trial of the case on the part of the people by the Hon. Thomas Penny, district attorney, and his assistant, Mr Haller, were well-nigh faultless Shortly after his arrest the district attorney procured from Czolgosz a statement several pages in length which was taken down in longhand, in narrative form, each page of which he signed after himself making corrections and revisions as to matters which he claimed the reporter had misapprehended This statement gave in detail facts concerning his premeditations and preparations for the crime, also his movements for some into the prisoner's mental condition and to report my conclusion to them as soon as I had reached one. They also assented readily to my proposal to invite Dr. Arthur W. Hurd to become associated with me professionally in the case, Dr. Hurd being the superintendent of the Buffalo State Hospital for the Insane and a competent alienist of large experience in mental diseases. It was also agreed that we should be allowed to confer freely with the district attorney and with the experts for the people after completing our personal examination of the prisoner. Being unable to establish communication with Dr. Hurd before evening of that day, and in view of the short time intervening before the trial, I decided to make a preliminary examination of Czolgosz alone, and did so that afternoon in the district attorney's office, first disclosing to him my identity and the object of my interview, and informing him of his legal right to decline to answer any question that I might ask him. I examined him again on the following day (Sunday) in the gaol jointly with Dr. Hurd and in the presence of one of his guards, who was questioned at length respecting his observations of him in the gaol, as to his habits of eating, sleeping, talking, reading, &c. We subsequently interviewed the district attorney and the superintendent of police, General Bull, who gave us all the facts and information in their possession respecting the case. The statement which Czolgosz made to the district attorney shortly after his arrest throws much light on his mental condition on the day of the crime, but that official deemed it his duty to refuse to allow me to publish it. We also conferred at length with the people's experts, Dr. Fowler, Dr. Crego, and Dr. Putnam, who stated to us separately and in detail their observations and examinations of him. We also observed him carefully in the court-room throughout the trial. After our examination of Czolgosz on Sunday we reached the conclusion, independently of each other, that he was sane, and we so informed his counsel on Monday morning before the trial began.

It should be said that owing to the limited time—two days—at our disposal prior to the trial, and the fact that his family relatives resided in a distant State and were not accessible for interrogation, we were unable to obtain a history of his heredity beyond what he himself gave us.

Czolgosz, as he appeared at the time of my examinations of him at Buffalo, may be described as a well-nourished, rather good-looking, mild-mannered young man with a pleasant facial expression; features regular; face smooth-shaven and symmetrical; mouth and ears well formed and symmetrical; teeth, none missing but in poor condition from neglect; tongue clean; palate, fauces, and uvula normal in appearance; eyes blue and normal in expression; pupils equal in size and normally responsive to light and accommodation; hair light brown and slightly curly; stature medium, five feet seven and a half inches; and weight, estimated, about 140 pounds. The extremities were in all respects normal. The external genitals were normal, excepting two small, flat, unindurated cicatrices on the mucous surface of the prepuce, probably the result of previous chancroids, although he denied having had venereal disease other than gonorrhœa. There were no signs of specific nodes or periosteal tenderness over the usual sites of these lesions, nor was there any evidence upon the head or body of traumatism, excepting a slight deviation of the nose due to a blow which he received at the time of the assassination and a superficial perpendicular cicatrix on the left face which he said was the result of a slight injury which he received when working in a barbed wire factory. There were no tremors or twitchings of the facial muscles, the tongue, or the hands. The pulse, the temperature, and the skin were normal, as also were the special senses, the knee reflexes, coördinating power, and the sensory and motor functions. Finally, a careful inspection of the entire visible body failed to reveal the presence of any of the so-called stigmata of degeneration. The almost perfect symmetrical development, especially of the head and face, is a noteworthy feature in Czolgosz's case, although had deviations been found the fact would have had little weight as tending to show mental disease or degeneracy, as marked asymmetries, both cranial and facial, are frequently observed in persons who are quite sane and are above the average in mental capacity. (Figs. 1 and 2.)

In answer to questions Czolgosz stated, in substance, that he was born in Detroit, Michigan, of Polish parents; that he was 28 years of age, was unmarried, and was a labourer by occupation; that he was a Romanist originally, but had abandoned that faith several years ago because he no longer believed in it; that he attended the common schools as a boy and had learned to read and to write; that he had used beer and tobacco, but not to excess; that he had done various kinds of unskilled labour such as farming, factory-work, &c.; that his mother was dead, and that his father, one brother, and a married sister were living; that, so far as he knew, there was no insanity in his family, and that he had not suffered any serious illness or injury during his life-time; that he had never been subject to fits, spasms, or vertigo; and that he usually ate and slept well, and that his bowels were always regular. He admitted having had sexual intercourse with women, but denied masturbation or other unnatural practices. Careful inquiry failed to elicit any evidence of delusion, hallucination, or illusion. When questioned as to the existence of enemies, persecutions, or conspiracies against him, he replied in the negative. He evinced no appearance of morbid mental depression, morbid mental exaltation, or of mental weakness or loss of mind; nor did he display any indication of morbid suspicion, vanity, or conceit, or claim that he was "inspired" or had "a mission to perform," or that he was subject to any uncontrollable impulse. In fact, as regards the existence of evidences of mental disease or defect, the result of the examinations was entirely negative. On the contrary, everything in his history, as shown by his conduct and declarations, points to the existence in him of the social disease, anarchy, of which he was a victim.

My last examination of Czolgosz was made jointly with Dr. Gerin, physician of Auburn Prison, the evening before his execution. This examination revealed nothing either in his mental or physical condition which tended to alter the opinion which I gave to his counsel at the time of his trial—namely, that he was sane—an opinion which was concurred in by all of the official experts on either side—namely, Dr. Fowler, Dr. Crego, and Dr. Putnam, for the people, and Dr. Hurd and myself for the defence, also by Dr. Gerin, the only other physician who examined him. Furthermore, the prisoner's manner, appearance, and declaration in the execution room, together with the post-mortem findings, corroborated most conclusively the original opinion as to sanity, while his dying declarations that he killed the President because he regarded him as "an enemy of the good people—the good working people," and that he was not sorry for his crime, all tend to stamp him as an anarchist. In fact, his bearing and conduct from the time of the commission of the crime to his execution were entirely consistent with the teachings and creed of anarchy. Moreover, neither the three careful personal examinations which I made of him—one alone, one with Dr. Hurd, and one with Dr. Gerin—the measurements of his body by the Bertillon system, nor the post-mortem findings, disclosed the slightest evidence of mental disease, defect, or degeneracy. This opinion is confirmed by the people's experts who repeatedly examined him and observed him from time to time from the day of the assassination to the close of the trial, and by Dr. Gerin, the physician of Auburn Prison, who observed him carefully during the four weeks that he was in that institution awaiting execution. Dr. Gerin has had exceptional opportunity for the study of criminals, both sane and insane, in his capacity as prison physician and previously as assistant physician at the State Hospital for the Criminal Insane.

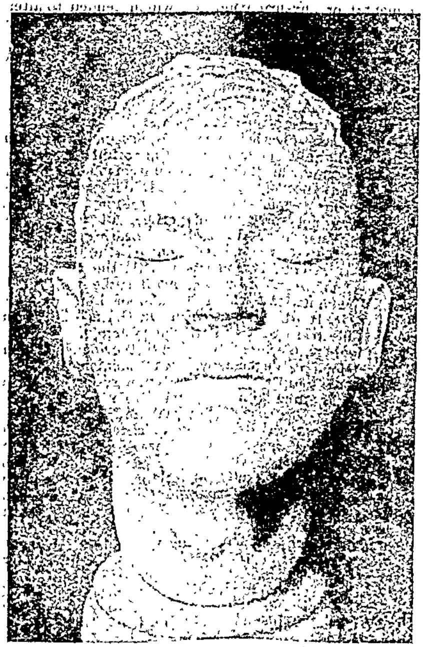
If Czolgosz was a victim of mental disease the question would naturally arise as to what form of that disorder he was suffering from. If in answer to this question we undertake to make a diagnosis by exclusion we find the following results. There was absolutely no evidence of insane delusion, hallucination, or illusion. There was none of the morbid mental exaltation or expansiveness of ideas that would suggest mania in any form, none of the morbid mental gloom and despondency of melancholia, none of the mental weakness of dementia, none of the conjoined mental or motor symptoms that are characteristic of paresis, nor was there anything in his manner, conduct, or declarations that would suggest the morbid vanity and egotism, the persecutory ideas or the transformation of personality which usually characterise paranoia or systematised delusional insanity. In fact, at no time during the period from his arrest to the time of his execution did he exhibit any of the mannerisms, boastful display, &c., or claim to have a "Divine inspiration" or "a mission," or make any complaint or suggestion of personal wrongs and persecutions

Dr. H. O. Ely of Binghamton, New York; Dr. W. A. Howe of Phelps, New York; Dr. G. R. Trowbridge of Buffalo, New York; Dr. W. D. Wolff of Rochester, New York; and Dr. C. R. Huntley of Buffalo.

### THE NECROPSY.

The necropsy was made by Mr. Edward A. Spitzka under the direction of the official physicians, Dr. Gerin and myself. The examination occupied about four and a half hours and embraced a most careful gross examination of all the viscera, attention being especially directed to the brain and its meninges. The accompanying masterly description of the post-mortem findings, and especially of the condition and anatomical structure of the brain, by Mr. Spitzka, leaves nothing to be said here upon this point beyond the fact that the necropsy revealed no evidence whatever of disease or deformity of any of the bodily organs, including the brain, which was normal in size, shape, weight, and appearance, and was well developed in all respects, a conclusion which was concurred in by all of the physicians present, several of whom had witnessed the execution. In deference to the expressed wish of the relatives of Czolgosz, and for reasons of a sentimental nature on the part of the State authorities, the prison warden declined positively to allow any portion of the body to be removed from the prison. Consequently, and regrettably, it was impossible for the examiners to retain honourable possession of any portion of the brain for microscopical examination and study. Accurate measurements, however, of the head and its appendages, of the face md of the exterior and interior of the skull, together with letailed anatomical drawings and descriptions of the brain vere made; also plaster moulds of the head from which a ast was subsequently made, and photographs of the same—full face and profile—were taken. These measurements, together with plates of the drawings and photographs, are presented in Mr. Spitzka's report of the necropsy.

FIG. 1.



Full-face view of the plaster cast of the assassin Czolgosz. Unfortunately the left ear in the mould had been broken during transportation from Auburn to New York, and the fragments were pieced together with difficulty. The defects have been rectified in the photograph. On the subject the ears were perfectly symmetrical both as to form and size.

In view of its great importance, both to medical science and to medical jurisprudence I regard it as fortunate that the State was able to secure the services of so able a brain anatomist and skilled operator and draughtsman as Mr. Spitzka to make the post-mortem examination.

### THE MENTAL STATUS OF CZOLGOSZ.

On Thursday, Sept. 19th, 1901, I received a telegram requesting me to meet Mr. Adelbert Moot, President of the Erie County Bar Association, in Buffalo, New York, on the following morning. On my arrival in Buffalo the next day Mr. Moot informed me that he had sent for me for the purpose of requesting me to inquire into the mental condition of Leon F. Czolgosz, confined in the Buffalo gaol under indictment for the murder of President McKinley, and whose trial was to begin on the following Monday. Mr. Moot further stated in substance that three local experts had already examined the prisoner for the district attorney, but in view of the enormity of the offence and the fact that there obviously could be no legitimate defence other than insanity it was deemed important in the interests of justice that his mental condition should be investigated by other experts acting in behalf of the defence, or at least independently of the prosecution, to the end that the prisoner should be accorded every legal right, there being no desire to convict him if he were not mentally responsible, and that I had been selected for this responsible duty. With a deep sense of the responsibility involved I consented to act, provided that it should be distinctly understood that I was not there as a partisan expert in behalf of either side, but simply in a professional capacity to aid in determining the real mental state of the prisoner, and providing, further, that my selection would be acceptable to the eminent counsel whom the Bar Association had selected for the defence, should they decide to accept that duty, a matter which was then undecided. On the following morning (Saturday) Mr. Moot informed me that the gentlemen referred to had consented to act and invited me to meet them in conference, which I did, and which resulted in their requesting me to proceed at once to examine

# THE AFTER-HISTORIES OF 100 CASES OF SUPRA-VAGINAL HYSTERECTOMY FOR FIBROIDS.

By G. CREWDSON THOMAS, M.D., M.R.C.P. Edin.,
LATE REGISTRAR, CHELSEA HOSPITAL FOR WOMEN.

Although much has been written recently about the operation of supra-vaginal hysterectomy for fibroids, comparatively little has been published about the after-results of this operation upon patients. For this reason I have conducted an inquiry into the after-histories of all the patients at the Chelsea Hospital for Women who have, during a definite period, had the operation of supra-vaginal hysterectomy performed on them. Unfortunately, I have been unable to carry my researches further back than May, 1896, as it was at that date that supra-vaginal hysterectomy commenced to be the operation of choice at Chelsea, and I have continued them up to June, 1900. During that time there are 117 cases available for investigation, of which the earliest ones have an after-history of five years and the latest ones of one year.

The study of the after-histories of operation cases is never an easy matter, since patients come to hospital from distant homes in the country and afterwards return, a fact which makes a personal interview with them almost an impossibility. A second difficulty is that the class from which hospital patients are drawn is constantly changing its abode and so an address which finds them one year will fail to do so the next. However, owing to the kind assistance of the staff I have been able to communicate with 100 out of the 117. The majority of these I saw personally; the remainder filled up a simple schedule which I had drawn up, and in several cases the patient's own medical attendants communicated personally with me and gave me valuable information. Of the 17 patients whom I was unable to trace personally five have been seen at the hospital at periods varying from two to three years and have all been in excellent health. The tabulated results of my inquiry are given in Table I.

Before taking up each subject and dealing with it individually three patients—Cases 4, 20, and 45—must be noticed. All these patients made successful recoveries from their operations and left the hospital in good health, but have since died. The patient in Case 4 died six months after operation quite suddenly from cerebral hæmorrhage The patient in Case 20 was noticed to have a weak heart when in the hospital, but she bore the operation well; about a year afterwards she died from heart disease. The patient in Case 45 at the time of her operation was suffering from Bright's disease; she likewise made a good recovery, but died two years after the operation from her renal trouble In no case can the cause of death be ascribed to the operation, and in the two cases last mentioned the condition had commenced prior to the operation Two patients, Case 11 and Case 56, are in asylums; as their statements are untrustworthy, they are not included, but their condition will be fully referred to later

*Present condition.*—The first point that I wished to investigate was the general result of the operation on the patient (1) from her own standpoint and (2) from her capacity for work As regards the former the verdict was remarkable in its unanimity; in every case except two the benefit resulting from the removal of the tumour had, in the patient's opinion, fully compensated for any evil sequelæ, such as severe artificial menopause, constant abdominal pain, trouble in the scar, &c. Many were enthusiastic as to the relief gained, stating that they had never been so strong in their lives before and that they were enjoying perfect health. The sole exceptions were the patient in Case 31 who, having a weak constitution, took some time to rally from the operation, and the patient in Case 75 who had always suffered from great depression; as the latter patient was physically strong and healthy her personal statement as to lack of benefit could hardly be relied upon.

On estimating their capacity for work we find that out of the 95 cases available—i e., excluding the three patients who died and the two who were mentally deranged—the result is as follows: 86 (or 90·5 per cent) of the patients were able to perform hard work with comfort, although 12 of these cannot continue to do so for long; eight (or 8·3 per cent.) were only able to do light work; and one, for an ulterior reason, could do none. Nothing more need be said as to the 74 patients who were able to do a whole day's hard work without becoming abnormally fatigued. The fact alone testifies to the value that the operation has been to them. Case 15 is of particular interest. The patient, a professional vocalist, had been warned against the operation as, it was said, she would lose her voice. A large fibroid and two cystic ovaries were removed, but her voice, instead of becoming weaker, has increased both in power and in compass. 12 patients, although they were able to do their ordinary work with comfort, yet found that any extra exertion caused them to be easily fatigued; the majority of them are patients who have been operated upon more recently and have not yet had time to reap the full benefit of the operation. There were eight patients who were unable to do their ordinary work with comfort. The patients who were the subjects of Cases 6, 22, and 67 belonged to a restless, hysterical type; prior to operation they never possessed much energy and subsequently they have only done light work. The patient in Case 31 had always suffered from severe headaches, and these incapacitated her; the patient in Case 62 had to lead a quiet life owing to cardiac weakness; while the subject of Case 63 suffered from a floating kidney and the patient in Case 98 had been crippled by chronic rheumatism. These four patients suffered from extraneous diseases, and as far as their operation goes complete success has resulted. In Case 34 the patient has become so stout that hard work is an impossibility, and she will be referred to later. Finally, the patient in Case 33, although in complete health, was incapacitated from any work owing to total blindness. It would be difficult to find any operation which has restored such a large percentage of women to sound health as is revealed in these figures.

*Post-operative pain.*—The question of post-operative pain is always an important one. Of these cases 61 patients had not experienced any abdominal pain since the operation, while 31 patients stated that they had had some pain in the abdomen. In many cases this had ceased within a year. In a few it was still present but it caused them little annoyance. As a rule it was indefinite in character and depended largely on the condition of the bowel, but in no case had it been of sufficient severity to make an invalid of the patient. That the operation may have been the cause of the pain in some cases is probable, but every abdominal pain subsequently to an operation cannot be put down to that operation. In three cases only—Cases 33, 67, and 69—was the pain of a periodical description and in all these cases one ovary had been left. It was not severe and will be referred to later.

*The condition of the cervix.*—The condition of the cervix which has been left behind has been a subject of much discussion, many maintaining that its presence is only a source of danger. In the majority of cases in which I made a vaginal examination I found that the cervix was absolutely normal in size, and had it not been for the bimanual examination it would have been impossible to diagnose that the corpus uteri was absent. In some cases the cervix was smaller than normal and was atrophied, more especially in unmarried women who had had both their ovaries removed Some continental writers, as Zweifel and Freund,[1] have described carcinomatous degeneration of the cervix as the result of leaving it. In none of these 100 cases was there any condition that would lead to a suspicion of malignant change commencing, and there is at present no evidence to prove that the percentage of women suffering from carcinoma cervicis is higher in those who have had supra-vaginal hysterectomy performed than it is in those who have never been operated upon.

In making investigation into the discharge that may have occurred from the cervix it was found that in 66 cases there had been no discharge. In 20 cases there had been some discharge, usually viscid and opaque, causing little inconvenience; it had ceased altogether in 11 cases. Nine patients had a periodical loss every month; the discharge was usually stained with blood and as a rule it lasted for from two to three days. In each case it is to be noted that one or both ovaries had been retained. Case 26 is curious in that the patient had a discharge every second month for two and a which are so characteristic of paranoiacs; nor did he, during his trial, or subsequently, evince any indication of satisfaction or delight at being the central figure of the occasion and the observed of all observers, which he was; nor was there any attempt on Czolgosz's part to simulate mental disease. The refusal to talk with his counsel was perfectly consistent with the views which he expressed to the district attorney soon after his arrest—namely, that he did not believe in law and that he wanted no counsel. He did, however, converse with others—namely, the district attorney from time to time before his trial, also with his guards at the Buffalo gaol, with whom he frequently walked in the corridor fronting his cell for an hour or two at a time, conversing with them intelligently the while and making his wants as to bathing, toilet, tobacco, &c, known in a natural manner. He also conversed freely with the people's experts in their earlier examinations of him, and talked, though not so freely, with Dr. Hurd and myself, and when on arraignment for trial and formally asked to plead he promptly arose from his chair and answered in a clear voice, "Guilty." He also responded promptly when directed by the clerk of the court to "stand up and look upon the juror" as each of the jurors was sworn, and resumed his seat in each instance at the proper time. Beyond this he remained mute while in the court-room, and yet to anyone who observed him closely it was apparent that he was fully aware of, and attentive to, the proceedings.

---

[1] German Gynæcological Congress, Berlin, 1899.

A recent writer—an eminent alienist—discussing the mental state of Czolgosz says:[1]

> We can perceive no indications of mental disease in Czolgosz, and were the absurdity of his statements and acts to be a criterion of mental unsoundness we should have to establish a new category of insanity for the reception of the various groups of anarchists, not to mention other terrorists. We deem it an error to regard Czolgosz's mutism in court when called on to plead and before his counsel as an attempt to simulate insanity. This conduct is in line with his rôle expressed in the theatrical declaration: "I am an anarchist and have done my duty." As it was his "duty" to slay the President it is his duty to go to death with his lips sealed, and with this intent first the plea of guilty and his conduct are perfectly consistent. He shows no reluctance to converse on matters disconnected from the crime, nor even of matters connected therewith provided they do not touch its preparations and thus betray his associates.

Aside from his reticence to his counsel there was nothing in Czolgosz's manner, appearance, or declarations that was indicative of insanity or of simulating. His reticence towards his counsel, as already intimated, was entirely consistent with his expressed disbelief in government and in law and his declaration that he shot the President with a clear knowledge of the nature and consequences of the act; and while he pleaded guilty in court and also proclaimed when he went to his death his reason for committing the crime, and declared that he was not sorry therefor in a manner which clearly implied that he regarded the act as a justifiable one, he did not claim that it was not a crime on his part, as paranoiacs usually do, nor did he in any way indicate that he regarded himself a victim of conspiracy or persecution. On the contrary, he declared to the people's experts that he fully understood what he did when he shot the President and was willing to take the consequences: "I know what will happen to me if the President dies—I will be hung." Justice White, commenting on Czolgosz's plea of "Guilty" when arraigned for trial—a plea which could not be accepted under the law—said: "The prisoner's plea of guilty indicates that he himself anticipates no escape from the penalty which the law prescribes for a crime of the character alleged in the indictment" Again, Czolgosz said: "I done my duty; I don't believe in voting; it is against my principles. I am an anarchist" He further said that he had been an ardent student of the doctrine of anarchy and had attended many "circles" where these subjects were discussed; that he had attended a meeting of anarchists "about six weeks ago" and also in July; that he had met and talked with an anarchist in Chicago about 10 days ago; that he belonged to a "circle" in Cleveland which had no name—"They called themselves anarchists"; and that he went to Cleveland "on no particular business" the Friday before the assassination He had been in Buffalo for two or three weeks prior to going to Cleveland "I planned to kill the President three or four days ago; after I came to Buffalo [from Cleveland] I don't believe in the Republican form of government and I don't believe we should have any rulers. I had that idea when I shot the President, and that is why I was there."

In explanation of his abandonment of his religious faith and his rejection of the services of a priest Czolgosz said the night before his execution: "I would like the American people to know that I had no use for priests. My family are all Catholics and used to go to church until the hard times of 1893. We had been taught by the priests that if we would pray God would help us along, but it did no good; it didn't help us and we stopped going to church at that time." He also said at this interview: "McKinley was going around the country shouting prosperity when there was no prosperity for the poor man. I am not afraid to die. We all have to die sometime."

It may be said that Czolgosz's belief which he expressed as he went to his death, that the President "was an enemy of the good working people," was a delusion, and such it undoubtedly was in the broadest sense of that term; that is, it was a false belief, but it was in no sense an insane delusion or false belief due to disease of the brain. On the contrary, it was a political delusion, so to speak—a false belief founded on ignorance, faulty education, and warped, not diseased, reason and judgment—the false belief which dominates the politico-social sect to which he belonged and of which he was a zealot, who in common with his kind believes that all forms of government are wrong and unnecessary—a body of malcontents whose teachings oppose all government and who advocate the use of violence to destroy the existing social and civil order of things. By his own admissions Czolgosz was a devout anarchist and a firm believer in the principles of "free society" as taught by Emma Goldman, of whom he was an ardent admirer, and others. These were the beliefs which furnished the motives for the murderous deed

That Czolgosz was an anarchist and was actuated in his crime by the motives which spring from the teachings of that sect are clearly shown by the following. 1. His declarations after his arrest—namely, that he did not believe in any form of government or law and that all rulers were tyrants who ought to be put down 2. His admissions to the district attorney that he was a member of anarchistic societies or circles and had frequently attended the meetings of the same; also that he had been influenced in his views by the "lectures" of Emma Goldman, and that when apprehended anarchistic literature was found on his person. 3. The recognition and commendation which he has received at the hands of anarchists at their meetings both in this country and abroad since his death, several of these societies having openly recognised him as such and lauded his action. The anarchists' creed teaches that when one of their number is selected to do a certain deed he is to proceed about it quietly and in his own way, taking no one into his confidence; that, having accomplished the deed, if apprehended he shall not admit his connexion with any other members of the circle; that if convicted and sentenced to die he shall go to his death without revealing his connexion with others, resting secure in the belief that he will be ever regarded by his associates as a martyr and a hero who died in the discharge of a noble duty. The course and conduct of Czolgosz from the beginning down to his death are entirely in keeping with this creed And, finally, the cool and courageous manner in which he met his death, and the fact that from the day of his arrest until he died he never uttered a word that could be used against his accomplices, if he had any, and that he died—as anarchists who suffer the death penalty always die—without uttering a word that would tend to incriminate any of his co-conspirators, all tend to stamp him as an anarchist.

Having viewed the case in all its aspects, with due regard to the bearing and significance of every fact and circumstance relative thereto that was accessible to me, I record the opinion unqualifiedly that Leon F. Czolgosz on Sept. 6th, 1901, when he assassinated President McKinley, was in all respects a sane man, both legally and medically, and fully responsible for his act.

*(To be continued.)*

**HEALTH OF HONITON RURAL DISTRICT.**—Dr F. M. Reynolds, the medical officer of health of the Honiton (Devon) Rural District, reports that in 1901 the deaths were 120 and the births 220, which, calculated on a population of 9318, corresponded to a birth-rate of 23·6 per 1000 and a death-rate of 12·8 per 1000.

| 68 | 31 | ,, 27th. | Right ovary retained; uninterrupted recovery. | Very good. | None. |
| 69 | 28 | April 3rd. | Right ovary retained; uninterrupted recovery. | Very good; slight periodical right-sided pain. | ,, |
| 70 | 39 | ,, 10th. | Left ovary retained; uninterrupted recovery. | Very good, since suffering from acute rheumatism in 1900 has had some white discharge. | Very slightly. |

TABLE I — SHOWING THE AFTER-RESULTS OF 100 CASES OF SUPRA VAGINAL HYSTERECTOMY FOR FIBROIDS.

| Case | Years of age | Date | Operation | Present condition | Artificial menopause |
|---|---|---|---|---|---|
| | | 1896 | | | |
| 1 | 34 | May 5th | Both ovaries removed, good recovery | Very good, slight left sided pain and yellow discharge for two months, none since | Moderate, almost passed off now |
| 2 | 45 | August 10th | Both ovaries removed, uninterrupted recovery | Very good | Moderate, for 10 months, ceased now |
| 3 | 52 | Dec 28th | Both ovaries removed, uninterrupted recovery | Very good occasional abdominal pain, for the first four months had a yellow discharge | Moderate, came on some time after leaving hospital |
| | | 1897 | | | |
| 4 | 41 | Jan 8th | Both ovaries removed uninterrupted recovery | Died six months after operation from cerebral hæmorrhage | — |
| 5 | 39 | Feb 19th | Both ovaries removed, uninterrupted recovery | Very good | Moderate, almost ceased now |
| 6 | 50 | March 1st | Both ovaries removed, secondary hæmorrhage on the fourteenth day, reopened, good recovery | Fair, but can only do light work | Slight still some giddiness |
| 7 | 48 | ,, 12th | Both ovaries removed, uninterrupted recovery | Good but soon tires and gets neuralgic pains in the abdomen | Severe, lasted two years |
| 8 | 45 | ,, 22nd | Both ovaries removed, uninterrupted recovery | Very good, has had slight left sided pain | Moderate; slight at times still |
| 9 | 41 | April 20th | Both ovaries removed, uninterrupted recovery | Very good, pain in the bladder and some yellow discharge for two years until a ligature was passed | Moderate almost ceased now |
| 10 | 43 | June 14th | Both ovaries removed, uninterrupted recovery | Very good | Moderate, ceased now |
| 11 | 41 | ,, ,, | Both ovaries left, uninterrupted recovery | Very good till June 1900 when the patient was removed to an asylum suffering from delusional insanity | — |
| 12 | 35 | ,, 27th | Both ovaries removed, uninterrupted recovery | Very good | Moderate, lasting 18 months |
| 13 | 39 | ,, 28th | Both ovaries left, good recovery | ,, ,, | None |
| 14 | 44 | July 8th | Left ovary retained uninterrupted recovery | ,, | Slight for two years |
| 15 | 33 | ,, ,, | Both ovaries removed uninterrupted recovery | ,, ,, | Very severe at first, less now |
| 16 | 42 | ,, 12th | Both ovaries removed, uninterrupted recovery | Very good, at times a slight yellow discharge | Moderate for two years, almost stopped now |
| 17 | 30 | ,, 22nd | Both ovaries removed, uninterrupted recovery | Very good, slight blood stained discharge for six months after | Moderate for six months after operation, none now |
| 18 | 32 | ,, 26th | Both ovaries removed, uninterrupted recovery | Good, but tires easily | Severe, not yet finished |
| 19 | 44 | Sept 3rd | Right ovary retained uninterrupted recovery | Very good | Slight; lasting for the first few weeks |
| 20 | 43 | ,, 6th | Both ovaries left, uninterrupted recovery | Very good for one year when the patient died suddenly from cardiac disease | — |
| 21 | 45 | ,, 10th | Both ovaries removed, uninterrupted recovery | Very good | Moderately for first year, none now |
| 22 | 48 | ,, 13th | Both ovaries retained uninterrupted recovery, | Fair has indefinite abdominal pains and had thick discharge for 10 months after operation | Moderately, less now |
| 23 | 51 | Oct 28th | Both ovaries removed, uninterrupted recovery | Very good | Slight, passing off |
| 24 | 31 | Nov 1st | Both ovaries retained thrombosis of the left internal saphenous vein, good recovery | Good, at times a yellowish discharge | None |
| 25 | 35 | ,, 29th | Left ovary retained, uninterrupted recovery | Very good | ,, |
| 26 | 45 | Dec 16th | Left ovary retained, uninterrupted recovery | Very good, slight show every second month for two and a half years after | None till two and a half years after the operation, since then moderate |
| | | 1898 | | | |
| 27 | 39 | Jan 17th | Right ovary retained uninterrupted recovery | Very good | None |
| 28 | 32 | Feb 11th | Right ovary retained, small pulmonary embolism, otherwise good recovery | Very good slight show every month lasting two days | None |
| 29 | 40 | ,, 14th | Both ovaries removed uninterrupted recovered | Very good, some pain in the abdomen for the first year with an intermittent yellowish discharge | Slight |
| 30 | 33 | ,, 25th | Left ovary retained; uninterrupted recovery | Very good, slight abdominal pains at times | None |
| 31 | 30 | ,, | Left ovary retained, uninterrupted recovery | Fair Incapacitated by severe headaches is weak and nervous occasional sharp abdominal pains | ,, |
| 32 | 33 | March 14th | Right ovary retained uninterrupted recovery | Very good; has a regular blood-stained discharge every month | |
| 33 | 38 | April 1st. | Right ovary retained uninterrupted recovery | Good as regards the operation Is totally blind slight pains every month for the first year | ,, |

years; she had had the right ovary removed, but retained the left. There were three patients—Cases 26, 38, and 46—who, having had a periodical loss for two or three years, ceased to lose at the respective ages of 47, 45, and 47 years, showing that when the uterus has been removed and the cervix is sufficiently large and healthy to make an attempt at menstruation, this discharge will cease at approximately the same age-limit as when the normal uterus is present and fulfilling its function. The remaining patients who have a periodical loss at present are all below the age of 44 years. In the later cases in which the stump has been much smaller, and in some of which the cervical mucous membrane has been completely removed, there has been no instance of this loss.

*The artificial menopause.*—The effect of the removal or the retention of the ovaries on the after-condition of a patient has been a subject of much discussion in recent years. The advantages of conservative hysterectomy were first advocated by Mr. Bland-Sutton[2] in 1897 and this method has now been adopted when possible by many operators. Some writers, however, still consider that the presence of the ovaries is an exaggerated benefit,[3] that the severity of the menopause depends solely upon the age of the patient,[4] and that when the ovaries are left behind they suffer from congestion, swelling, and subsequent adhesion.[5] The uncertainty in the normal menopause makes it difficult to form a standard by which to judge the artificial. Just as no two women suffer equally in their normal menopause, so it is true that no two women experience the same sensations in an artificially induced menopause. For this reason it is impossible to form any conclusions or to make deductions from a few isolated cases; a large number must be used from which a normal standard may be adduced, so that individual idiosyncrasies may be judged from their true standpoint and be classified as abnormal when found to deviate from that which occurs in the majority.

In the present statistics I have classified the condition of the patient under five divisions. The first class is those who have had "none" of the phenomena of the menopause since the operation. The second class is those who have experienced it only very slightly; by this is meant those in whom the phenomena were so mild that the patient was hardly conscious of them. The third class is "slight"—those in whom the phenomena were more definite; they never caused much trouble, but the patient realised their presence The fourth class is "moderate"—those in whom the symptoms caused the patient considerable discomfort but never obliged her to cease her occupation. Lastly, "severe," in which the patient suffered from constant heats and flushes, headaches, and giddiness, which at times incapacitated her from work and caused great distress. The condition of the patient has been estimated as much as possible when they were at their worst. Three patients—Cases 26, 38, and 43—who only commenced to experience climacteric symptoms from two to three years after the operation have been classified as "none," and will be mentioned later.

Statistical results as to the severity of the artificial menopause are few and have been classified either—as by Kelly,[6] Werth,[7] Doran,[8] and Burckhard[9]—simply according to retention or otherwise of the ovaries, or else—as by Jordan[10]—according to the age of the individual. In Table II. both these factors have been taken into account, as the importance of the ovaries varies according to the age of the patient I have classified the ovaries into two groups, "removal" and "retention," and have divided the years into decades, except between the important ages of 40 and 50 years, where they have been further subdivided. Of the 95 cases that are available for investigation we find that in 36 patients both ovaries have been removed and in 59 one or both ovaries have been retained. If these cases are tabulated according to the severity of their menopause, we get the result as shown in Table II.

In Table II. it will be noticed that of the 36 cases in which both ovaries were removed every patient, except one, suffered more or less from an induced menopause, whereas many of those who had an ovary retained experienced no such symptoms. In considering those who have lost both their ovaries we find that two were between the ages of 20 and 30 years. The first patient, Case 94, who had only experienced slight symptoms, had had both her ovaries removed for disease nearly one year previously to her hysterectomy. In consequence she had already passed through the worst of her artificial menopause before her second operation; for this reason her case cannot be taken as giving a straightforward result. Between the ages of 30 and 39 years there were 11 cases. Seven of these patients, or 63·3 per cent., had experienced moderate symptoms, and four, or 36 3 per cent., had suffered from severe symptoms of their menopause. Between the ages of 40 and 44 years there were 12 patients. Four, or 33 3 per cent., suffered slightly; five, or 41 6 per cent., suffered moderately; and three, or 25 per cent., had severe symptoms Between the ages of 45 and 49 years there were seven patients. One patient, or 14·2 per cent., suffered slightly; five patients, or 71·4 per cent., moderately; and one, or 14·2 per cent., severely. Above the age of 50 years there were four patients. One only (Case 86) had both her ovaries removed and she experienced no ill-effects. This patient was 56 years of age when she was operated upon and she had passed through the menopause four years previously. Of the others two had suffered slightly and one moderately.

In turning to the 59 cases in which one or both ovaries had been conserved we find that not one of the three patients between the ages of 20 and 29 years had experienced any vasomotor disturbance. Between the ages of 30 and 39 years 23 patients had been operated upon Of these 18, or 78 2 per cent., had had no symptoms whatever; four, or 17·4 per cent., had been conscious of very slight disturbance, but practically of no importance; and one, or 4·3 per cent, had had slight symptoms. Between the ages of 40 and 44 years 20 patients were under observation. Of these 12, or 60 per cent., had had no symptoms; two, or 10 per cent., had suffered very slightly; three, or 15 per cent., had had slight symptoms; and three, or 15 per cent., had suffered moderately from flushes and heats and their concomita Between the ages of 45 and 49 years 10 patients had been operated upon. Of these four, or 40 per cent, had had no symptoms; two, or 20 per cent., had suffered slightly; two, or 20 per cent., moderately; and two, or 20 per cent., severely. These last two patients (Cases 42 and 50) were aged respectively 47 and 49 years. The patient in Case 50 had commenced to experience the ordinary symptoms of the menopause about two months prior to the operation; since the operation the menopause had been very severe. There were three patients over 50 years of age. Two had had no symptoms of the menopause and had not noticed any previously to their operation and one patient had slight symptoms. In comparing the percentages of the two sets of cases from their ovarian standpoint alone we get the following results (Table III.):—

TABLE III.

| Severity of the menopause. | Ovaries removed. | Ovaries retained. |
|---|---|---|
| None ... ... ... ... ... .. ... | 0 per cent. | 66 per cent. |
| Very slight ... ... ... ... ... | 0 ,, | 10 1 ,, |
| Slight . ... .. ... ... ... ... | 22·8 ,, | 11·8 ,, |
| Moderate ... ... ... ... ... ... | 54·2 ,, | 8·4 ,, |
| Severe . ... ... ... ... | 22 8 ,, | 3·3 ,, |

Table III. shows the advantage of keeping the ovaries as a general principle, irrespectively of age. If we now compare the results, taking into account the age of each patient, we get a still more striking result (Tables IV., V., and VI.):—

TABLE IV.

| Severity of the menopause. | 34 patients between 30 and 39 years of age. | |
|---|---|---|
| | Ovaries removed in 11 cases. | Ovaries retained in 23 cases. |
| None .. .. ... ... ... ... ... | 0 per cent. | 78 2 per cent. |
| Very slight ... ... ... ... ... | 0 ,, | 17·4 ,, |
| Slight .. ... ... ... ... ... ... | 0 ,, | 4·3 ,, |
| Moderate ... ... ... . ... ... | 63·3 ,, | 0 ,, |
| Severe . . .. ... ... .. .. | 36 3 ,, | 0 ,, |

| Severe . ... ... | — | 4 (36 3°/o). | 3 (25°/o) | 1 (14 2°/o) | — | — | — | — | 2 (20°/o) | — |

bowel or bladder, but on investigating these cases we find that only two patients suffered from lack of proper control over the bowel; they were usually constipated, but when by artificial means the bowels were opened they were unable to control them. As regards the urinary system, eight patients have had some trouble in micturition since the operation—in one case a ligature being passed per urethram—but this trouble has in every case ceased after the first year.

*Sexual instincts.*—The influence of hysterectomy, with or without conservation of the ovaries, upon the sexual instincts is a subject about which little is known and upon which great diversity of opinion exists. Out of the 95 patients 64 were unmarried, widows, or living apart from their husbands, but of the remaining 31 we find that in 19, or 61·2 per cent., the marital relations were unaltered (seven of these had had both ovaries removed). Nine of the patients, or 29 per cent., stated that their relations were not so good as formerly (only two of these had had both ovaries removed); and three, or 9 6 per cent., found these relations improved; of these three patients the one who had this characteristic most markedly had had both her ovaries removed. From these facts neither the uterus nor the ovary appears to be essential for sexual instincts. The only factor which seems to have any bearing upon the condition is age. In those in whom a change had occurred the ages in seven cases were over 40 years and the remaining two patients were only just under that age, whereas three-fourths of those who had experienced no change were under 40 years of age. Whatever the cause may be, in the vast majority of cases hysterectomy does not interfere with the sexual passions.

*Conclusions.*—In recapitulating the most prominent conclusions it may be stated that from the standpoint of the patients the operation is an eminently satisfactory one and their capacity for work is greatly increased. The statistics clearly demonstrate that one ovary should be retained, but that the importance of this diminishes in proportion as the age of the patient approaches more closely the climacteric period The operation *per se* causes no tendency to insanity, but a certain number of patients complain of a diminution in their powers of memory. The pain and discharge resulting from the operation are very slight; the functions of the bowel and bladder are not usually interfered with, and the sexual sensations, as far as can be gathered, are not generally influenced by the operation.

In conclusion, I must express my indebtedness to the staff of the Chelsea Hospital for Women, who so kindly placed their patients at my disposal and without whose assistance this investigation could not have been made.

London.

# A CASE OF RECURRENT SARCOMA WITH APPARENTLY SPONTANEOUS CURE AND GRADUAL SHRINKING OF THE TUMOUR.

BY A. LAURIE WATSON, M.A., M.B., CH.B. GLASG.,
LATE RESIDENT ASSISTANT SURGEON, ROYAL INFIRMARY, GLASGOW.

THE following case seems to derive an exceptional interest from the fact that, so far as I can gather from the literature, nothing similar has been recorded. The facts have been carefully revised and all possible sources of error eliminated; indeed, in view of the unusual and unexpected result, I have been sceptical of everything that could admit the least suspicion. Coley,[1] in his article on the treatment of malignant tumours by mixed toxins and cultures of streptococcus erysipelatosus and bacillus prodigiosus, collects statistics of cases thus treated, and if his figures are at all accurate the results are certainly impressive; but after referring to the analogous cases in which cure has resulted from a supervening attack of erysipelas he goes on to add: "It would be somewhat remarkable that these cases should be the first, and thus far the only ones with both clinical and microscopical diagnosis of malignancy to disappear spontaneously, and it would be more remarkable still that this disappearance should be coincident with the beginning of the treatment with the toxins." Now, unless there has been some gross error of observation or deduction, the case here recorded stands quite apart from those of Coley, for there was no injection of toxins or any spontaneous attack of erysipelas, yet the tumour shrank in a most remarkable manner, and so far as its malignancy is concerned may be regarded as cured.

The patient, a strong, healthy-looking woman, aged 36 years, married, and with two children, was admitted to the Glasgow Royal Infirmary on Nov. 21st, 1900. She was absolutely free from ailment, and came into the hospital simply because a swelling on the back was annoying her and she wished to have it removed. This tumour was large and pendulous, being attached to the left side of the back by a base nine inches wide and rather less than four inches in vertical measurement; the apex hung down for almost four inches below the lower margin of its attachment to the back, while the upper margin was just below the inferior scapular angle. It was soft, but not fluctuant, slightly nodulated, and had the appearance of a lipoma undergoing degeneration; the skin covering the dependent portion was of a dark reddish colour. The tumour was regarded as simple, partly because of its character and partly because its history went back to the patient's childhood, though it had grown considerably in recent years.

On Nov. 23rd Dr. D. McK. Dewar, acting for Dr. D. Newman, removed it freely with all the discoloured skin, and remarked at the time that in three respects it differed from an ordinary lipoma: (1) the tissue was of a dirty greyish-yellow colour and very friable; (2) it was exceedingly vascular; and (3) its margins were diffuse and indefinite. After the operation hæmorrhage was so free that the dressings had to be frequently changed in the first few hours; thereafter they were left for four days untouched. On the 27th it was observed that the dressings had become tight and on exposing the back the tumour was found to be almost as large as before operation In the expectation that this might be due to accumulation of blood-clot beneath the flaps a portion of the wound was opened up, but no blood could be expressed, even when a director was introduced and worked about inside the wound. It was therefore concluded that the swelling was due to a rapid re-formation of the tumour. By an unfortunate oversight the tumour first removed had been destroyed without microscopical examination; but at this stage two small portions of the tissue were removed. One of these I hardened and stained myself, the other was sent to Dr. C. Workman, pathologist to the infirmary. The sections obtained from the first portion were examined by Dr. Newman, by Dr. Dewar, and by myself; and the recognition of sarcomatous tissue, chiefly round-celled, was unhesitating. Dr. Workman's quite independent report described the tissue as a mixed round-cell and spindle-cell sarcoma.

A week later the operation wound had begun to ulcerate along its margins, and it was decided to attempt a wider removal, but when on Dec. 4th the patient was placed on the table and anæsthetised, the tumour had attained such a size and was so diffuse in its margins that further radical interference was considered out of the question; the ulcerated edges were therefore cut away and the wound was again stitched up. During the remaining days of her residence in the infirmary the patient looked and felt very ill and weak. A bad prognosis was given and she was dismissed on the 13th. After this several medical men saw her and all took a gloomy view of the case; but in spite of everything she improved and a month after dismissal from the hospital a letter was received from her own medical attendant stating that the operation wound had almost completely healed. When I visited her at her home in the country on Feb. 9th, 1901, I reported as follows: "The operation wound has entirely healed up, with only a small scab at its lower extremity, and leaves a firm healthy-looking cicatrix. The tumour is much less tense than at the time of dismissal and shows a tendency to return to the pendulous form which it had when first seen; it is flaccid and quite painless. At its anterior margin are some subcutaneous livid patches which were noticed at the time of the recurrence of the tumour, but these do not appear to have changed at all or to be spreading. The patient's general condition is much improved; she is able to be up and about, eats with a good appetite, and in general feels very comfortable." She again reported herself at the infirmary in April and the tumour seemed to be still further diminished in size.

---

[1] Twentieth Century Practice, vol. xvii.

A remarkable difference is noted by Table IV. which shows the extreme value of the ovaries in warding off the symptoms of an artificial menopause at this age.

TABLE V.

| Severity of the menopause. | 31 patients between 40 and 44 years of age. | |
|---|---|---|
| | Ovaries removed in 11 cases. | Ovaries retained in 20 cases. |
| None ... ... ... ... ... | 0 per cent. | 60 per cent. |
| Very slight ... ... ... ... | 0 ,, | 10 ,, |
| Slight ... ... ... ... ... | 33·3 ,, | 15 ,, |
| Moderate ... ... ... ... | 41·6 ,, | 15 ,, |
| Severe ... ... ... ... ... | 25 ,, | 0 ,, |

The same difference is to be noticed here also, but not to such a marked extent.

TABLE VI.

| Severity of the menopause | 17 patients between 45 and 49 years of age. | |
|---|---|---|
| | Ovaries removed in 7 cases. | Ovaries retained in 10 cases. |
| None ... ... ... ... | 0 per cent | 40 per cent |
| Very slight ... ... ... | 0 ,, | 0 ,, |
| Slight ... ... ... ... | 14·2 ,, | 20 ,, |
| Moderate ... ... ... ... | 71·4 ,, | 20 ,, |
| Severe ... ... ... ... | 14·2 ,, | 20 ,, |

Between these ages the percentage is still slightly in favour of retaining the ovaries although their value here has decreased greatly. The menopausal symptoms which have occurred in some of the older patients in whom the ovaries were retained may probably be ascribed not so much to the effect of the operation as to the onset of the natural climacteric.

Considering these tables as a whole, the striking value of the presence of an ovary in warding off the severity of an artificial menopause is very clearly demonstrated, and although there is no definite rule which applies to every patient without exception yet there is a governing principle. There is a ratio between the age of the patient and the severity of the menopause. The younger the patient who has her ovaries removed the more severe will be her artificial menopause; as the patient becomes older the nearer will the artificial menopause resemble the normal climacteric. If the ovaries be retained the induced menopause is practically avoided below the age of 40 years, above that age the ovaries decrease in value every year. It may safely, then, be stated that the artificial menopause is dependent upon two factors—the removal or the retention of the ovaries and the age of the patient.

If, on the other hand, we examine these 100 cases for ill-results following the retention of the ovaries we find that in no case has their presence threatened to invalidate the success of the operation. In examining the 31 cases, which included every patient who had had any form of abdominal pain since operation, we find that 13 come from the 36 cases who had both ovaries removed and 18 from the 59 in which both ovaries were retained; the proportion of painful symptoms being less in those with ovaries, the pain cannot be indiscriminately ascribed to their presence. In three cases alone was there slight periodical abdominal pain every month. Therefore, in comparing the advantages to be derived with the risks that are involved in the retention of the ovaries, there is no doubt but that the advantages far outweigh the very slight possibility of future trouble that may be occasioned by their presence.

It has been a matter of some speculation as to what happens to the ovaries when they are left in the pelvis. From these cases it seems probable that in certain patients they continue to perform their functions in the same manner as formerly, but in a less degree. The monthly cycle of the patient's life remains unchanged, ovarian influence continues, and in some cases, where there has been sufficient uterine tissue to secrete left behind, there is an attempt at menstruation, as has been formerly mentioned. In other cases—such as in Cases 33, 67, and 69—there is a certain amount of discomfort and pain periodically every month. How long an ovary under these changed conditions will continue to exercise its influence over the system is uncertain, but in three cases—Cases 26, 38, and 46—the periodical discharge ceased about the age of 46 years. These patients then underwent a normal climacteric. This, however, is not always the case, as is shown by the fact that a certain number of patients, although their ovaries have been conserved, yet have experienced some symptoms, though slight, of the menopause soon after operation. It may be that in these cases the ovary has become in some way injured by the operation and its vitality impaired; if this is so, it would also seem that the older the patient the more easily is this ovarian function interfered with. In several cases the ovaries were removed because they were markedly diseased, but this pathological condition has not in any way mitigated the severity of the ensuing artificial menopause. Two patients only—Cases 34 and 49—complained of obesity since their operations, and in Case 34 this increase in weight prevented the patient from doing hard work. In both cases the ovaries had been removed.

*The mental condition.*—There has always been a recognised relationship between the uterus with its appendages and the mental condition. On investigating these cases with a view to finding out any change that may have occurred subsequently to operation it is noticed that in the majority of cases there has been no change in their mental attitude; in a few depression and irritability have been complained of, but this usually existed as a concomitant of the menopause. Two patients, however—Cases 11 and 56—require special notice, as they are inmates of asylums. The former of these was operated upon on July 14th, 1897. It was a case without complications and both ovaries, being in a healthy condition, were left *in situ*. While in the hospital the mental condition of the patient was unstable, but she made a good recovery and returned to her former situation as a domestic servant. Her health improved greatly and she remained in her situation until May 4th, 1900—a period of nearly three years. She then had to be removed to an asylum suffering from melancholia. I am indebted to the medical superintendent of the County Asylum, Brookwood, for the following particulars of her present condition. He states that she is depressed and miserable, hears supernatural voices talking to her, and that she has lately developed sexual delusions. He adds that in his opinion the operation could only have had a beneficial effect. This patient seems to have had a tendency towards insanity which developed irrespectively of her operation. The other patient was operated upon in November, 1898 In her case both the ovaries were removed, but nothing abnormal was noticed in her mental condition. She made an uninterrupted recovery and went out to service as a lady's maid; she was quiet and bright and for 18 months was in very good health. The lady with whom she lived died suddenly; this seemed to upset her very much and in October, 1900, she had to be placed in the Three Counties Asylum. The assistant medical officer of that institution has communicated with me, and in his opinion her present mental condition is not the effect of the operation. Eccentricity and delusional insanity seem to have been present before and after operation. She has delusions that her food is poisoned and she also has hallucinations In both these patients we find an unstable condition prior to the operation,[11] and their present state cannot be considered as a direct result of the operation.

*Memory.*—Although the mental condition seems to be unaffected by the operation, yet it is interesting to note that the power of memory in many cases does not seem to be so good. Out of 95 patients 34 complained that their memory was less retentive than formerly. In six of these the loss had only been temporary, lasting two or three years, but in the remaining 28 there had been a permanent diminished power since the operation. 14 retained their ovaries and 14 had lost them, being a percentage of 23·5, as against 33·6 in favour of retention of the ovaries. The reason for this loss is, however, obscure, as advancing age can hardly be made to account for so large a percentage.

*Bowel and bladder complications.*—Operations upon pelvic tumours always entail the risk of a possible injury to the second day after the operation the patient complained of very great thirst he was allowed to sip a few teaspoonfuls of water. This was followed by no ill-effect, so on the next day milk was substituted for the water. Two days later he was given beef-tea, and at the end of the week he was allowed to have solid food. The patient made an uninterrupted recovery and was discharged completely cured, the cough, dyspnœa, and other symptoms having entirely disappeared. From the time of the operation until his discharge the temperature never rose above normal.

## NOTES ON A CASE OF VARIOLA HÆMORRHAGICA.

W. CULVER JAMES, M.D. ABERD., F.R.C.S. EDIN.,
SENIOR PHYSICIAN TO THE WESTMINSTER GENERAL DISPENSARY.

THE patient, a governess, was first seen on Jan 7th last, complaining of chill, pain in the back, and nausea. She had nasal and bronchial catarrh and a slight cough; the tongue was furred, the menstrual period was overdue, her temperature was 103° F., and her pulse was 108. She had recently been working rather harder than usual and had felt tired and weary. On the day before she was seen she suffered from backache which became so severe that she was unable to sleep and could with difficulty turn in her bed. She was suffering from constipation for which an aperient had been administered. On the evening of Jan. 7th the pain was relieved and she passed a good night. On the following day the catamenia appeared, the temperature fell, the pain in the back was less, and she felt much better. Towards night the uterine discharges became profuse and offensive; later an eruption appeared on her face. On Jan. 10th the skin of the whole of the face was red, inflamed, swollen, and covered with minute vesicles, giving the idea of a uniform scalding. Scattered over the neck, trunk, arms, and thighs were numerous small vesicles about a line in diameter, with reddened bases. Interspersed among these were a very few larger vesicles with small dark-brown centres; only about half-a-dozen were counted. The tongue was coated with a thick white fur and on the left of the palate was a vesicle of a dark-brown colour, of about a sixth of an inch in diameter. The catamenial discharges remained profuse and of a foul character, and she was expectorating blood-stained mucus. She was removed to the hospital in the evening, but the hæmorrhage from the uterus continued and that from the lung increased. She died on Jan. 13th.

On careful inquiry the following facts were elicited Six months before the patient was born her mother had suffered from a severe attack of small-pox, from which, however, she made a good recovery. The patient was born at full term, the skin showing several cicatrices—"small-pox pits." In infancy she was vaccinated and revaccinated unsuccessfully. When she was nine years of age she was vaccinated three times unsuccessfully and at the age of 14 years she was again vaccinated without result. With such an experience her parents naturally thought her immune, and she was unfortunately not vaccinated when small-pox broke out last year. A fortnight before she began to be ill she came in actual contact with an acquaintance who had come straight from a case of hæmorrhagic small-pox (that afterwards ended fatally).

The above case is interesting as it would appear to show that variola in intra-uterine life had rendered the patient insusceptible to vaccination for 14 years, but that after a period of 18 years it had afforded no protection against a fresh attack.

Marloes road, W.

NEWTON ABBOT HOSPITAL.—The annual meeting of the subscribers to this institution was held on Jan. 23rd. The medical report stated that 224 in-patients had been admitted in 1901, compared with 220 in the preceding year. The out-patients numbered 872. The financial statement showed that the receipts amounted to £1391, including £163 from the Hospital Saturday Fund. The expenditure was £1143.

## EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

### A CASE OF PERSISTENT OMPHALO-MESENTERIC DUCT; LAPAROTOMY; RESECTION OF THE DUCT; RECOVERY.

(Under the care of Mr. H. BETHAM ROBINSON.)

AN umbilical fæcal fistula resulting from patency of Meckel's diverticulum is somewhat rare. Probably in these cases the patent duct extends into the cord and is tied with the cord, so that when the cord separates an opening lined by mucous membrane is left. The degree of prolapse of the mucous membrane of the duct varies in different cases. It may form a prominence two inches in length. Mr. W. H. Battle showed a case at the Clinical Society of London[1] in which a very similar condition existed.

The little boy in whom the above condition was present was first taken to the East London Hospital for Children when he was a few months old. The history given was that at birth the cord was noticed to be very thick at its attachment and after its separation some fæcal discharge came from its surface. Very soon what seemed like a red polyp appeared on the umbilical cicatrix. The discharge from its apex was yellow like that from the small intestine, but its amount varied; it was occasionally tinged with blood due to the bruising of the surface of the polyp. The child was inclined to be constipated. Nothing abnormal could be felt on palpating the abdomen. A probe could be easily passed through the centre of the polyp, evidently into the intestine, proving that there was a persistent duct with prolapse of its mucous lining. As the child did not seem very robust Mr. Robinson thought it wiser to postpone the operation for a while, but when the patient was 13 months old, as he seemed to be much stronger and fearing lest its postponement should allow of the production of a difference in calibre of the lumen of the bowel on each side of the attachment of the duct, Mr. Robinson decided to operate.

The operation was performed under chloroform on June 13th, 1901. A vertical incision was made in the linea alba, starting about one inch above the umbilicus, then passing round the left side of the latter to the mid line to end one inch below. The fascia was divided and the peritoneal cavity was opened; a similar incision was made on the right side of the navel, thus freeing the umbilical cicatrix and leaving it attached to the duct. It was then shown that there had been an extension of the peritoneal sac into the base of the umbilical protrusion, the duct being centrally placed and completely surrounded by the sac. The tube was three and a half inches long, joining the free border of the small gut at right angles; there was a delicate mesentery on either side of the process attached to the gut at right angles to its long axis. As was anticipated the lower end of the gut was slightly reduced in size, although the calibre of the duct itself was not sufficient to divert the contents of the intestine to any extent. The process was next clamped inside its skin attachment and an incision was made round it through the serous and muscular coats about one inch from the bowel The latter coats were peeled back with a blunt dissector; the tube of mucous membrane was ligature and cut away. The sero-muscular sleeve was sewn up over the stump by Lembert's sutures in the long axis of the gut. The operation was completed by stitching up the abdominal wall in layers, there being of course now no umbilical cicatrix. Although the operation did not take very long there was considerable collapse but the child rapidly revived with brandy and strychnine.

The after-progress of the case was exceedingly satisfactory.

---

[1] Transactions of the Clinical Society of London, vol. xxvi., p. 237.

As I have already stated, there was nothing of the nature of an attack of erysipelas in this case; but although locally no inflammatory phenomena manifested themselves the details of the temperature chart are suggestive. For the first six days after admission the temperature records showed a subnormal and normal range with a minimum of 97·2° F. and a maximum of 98 6°, being quite unaffected by the operation on Nov. 23rd, 1900. Then during the following week a slight upward tendency was noted, a maximum of 99 8° being registered on Dec. 3rd, and after the second visit to the theatre (on the 4th) the temperature shot up to 101·8°, remaining febrile and subfebrile, with daily remissions for five days, the highest point reached being 102° on the 8th From the 10th to dismissal on the 13th it was practically normal Whether this post-operative fever was an important factor in determining the subsequent resolution of the tumour I cannot pretend to say, but certainly the progress was continuous and most satisfactory.

Finally, I again visited the patient at her home on Nov. 21st, exactly a year after her admission to the infirmary, and the following is my report: "The general health is excellent. The tumour is much less prominent and hangs like a loose sac, as if almost all its contents had been evacuated There is slight lividity at the margins but no pain, except an occasional stinging like neuralgia in damp weather. The tumour covers about the same area as at the time of dismissal but consists of little more than loose skin. The scar of the operation wound is perfectly sound and firm. No pain is caused by free manipulation and the clothes are worn without discomfort"

The recorded cases of sarcomata which have disappeared after an attack of erysipelas are fairly numerous. One such has come under my own observation. It was that of a man under the care of Dr. J McC. Johnston in the Town's Hospital, Glasgow, and at the time it impressed me greatly. First of all, a small rounded tumour of about the size of a walnut was removed from beneath the chin and microscopical examination showed it to be a round-cell sarcoma. A few weeks later the patient returned with a chain of greatly enlarged glands on both sides of the neck. Dr. Johnston dissected away all the tumours on one side in a first operation, and just as he was ready to deal with the other side the patient developed a violent attack of erysipelas all over the neck and upper part of the chest, and with the clearing up of this the glandular swellings also disappeared. From such cases as this the treatment by toxic injections was a natural corollary, but in this country it does not appear to have been systematically and persistently tried with any measure of success. Yet the analogy between sarcoma as a morbid overgrowth of connective tissue and simple inflammatory hyperplasia seems to indicate a rational basis for such treatment, and certainly much progress may yet be made in this direction

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A BRIEF NOTE ON THE USE OF PETROLEUM EMULSION AS AN INTESTINAL DRUG.

BY THEODORE FISHER, M.D., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, BRISTOL HOSPITAL FOR SICK CHILDREN; PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY.

IN a letter to THE LANCET of Nov. 23rd, 1901, p. 1448, commenting upon the morbid anatomy lesions of typhoid fever, I suggested that petroleum emulsion might be found useful as an intestinal antiseptic in that disease. At that time I had not tested the value of the emulsion in the laboratory, but a few experiments undertaken since seem to show that when mixed in equal quantities with ordinary culture media it has no power to restrain the growth of either aerobic or anaerobic micro-organisms. My belief in the value of petroleum emulsion was based upon the experience of the out-patient room where one is exposed to many fallacies. One instance, however, where this emulsion was used in chronic diarrhœa is worth mentioning.

A child, aged two years, when brought to the hospital was said to be having about 12 motions a day. The patient was given two drachms three times daily of a medicine composed of equal parts of a simple chalk mixture and petroleum emulsion. At the end of a week the bowels were said to have been opened on an average from two to three times a day. There was then no petroleum emulsion in the dispensary and the child was given one and a half drachms of the chalk mixture three times a day, but at the end of the second week the diarrhœa was nearly as bad as before treatment was commenced. One grain of beta-naphthol was added to two-drachm doses of the chalk mixture, but at the end of another fortnight the bowels were still moved eight or nine times a day. The mixture containing one drachm of petroleum emulsion was then given again and the frequency of the motions immediately fell to twice a day.

In the treatment of threadworms petroleum emulsion has often seemed to me to be useful. A curious case may be mentioned which came under the observation of my colleague. Dr Cecil Williams A young woman, aged 25 years, had suffered from threadworms for about 15 years and had been under the care of several medical men for the complaint. At my suggestion Dr. Williams tried petroleum emulsion and after it had been taken for about three weeks the worms had ceased to trouble her. I have not, I regret to say, investigated in any reliable way the value of petroleum emulsion in the treatment of threadworms. Children are rarely brought up to a hospital for them alone and when the worms disappear while the child is taking the emulsion the medicine given for the primary disease may be the responsible remedial agent in the minor complaint. My belief in the power of petroleum emulsion to get rid of these worms is somewhat shaken by finding that the emulsion does not possess bactericidal power. If in some cases of diarrhœa petroleum emulsion is of real, not merely of apparent, value the explanation may be that it has some beneficial mechanical action upon the walls of the intestines. It is worthy of note, however, that naphtha has been thought by physicians practising in the East to be of value in the treatment of cholera. One can conceive it to be possible that there may be forms of petroleum less volatile than naphtha, but sufficiently volatile to be antiseptic when used in considerable quantity, yet which, when used internally, would, like the oil contained in petroleum emulsion, pass through the intestines without being absorbed

Clifton, Bristol

### SIX MONTHS' IMPACTION OF A COIN IN THE ŒSOPHAGUS; SUCCESSFUL REMOVAL BY PROBANG.

BY CHESNUT PEACOCK, M.B., B.CH. R.U.I.,
HOUSE SURGEON, MILLER HOSPITAL, GREENWICH ROAD, S.E.

ON Dec. 21st, 1901, a boy, aged six years, was admitted into the Miller Hospital, Greenwich-road, S E, suffering from brassy cough and regurgitation of food, accompanied by rise of temperature The history elicited the fact that in the previous July the patient had swallowed a halfpenny. Vomiting occurred immediately afterwards but was not repeated. For the next three weeks the patient said that he could "taste the ha'penny," and he complained of pain under the chin every time he took food; but at the end of that period these symptoms ceased, and until December the patient suffered no further inconvenience. At the beginning of December a dry, clanging cough, difficulty in swallowing, dyspnœa, and regurgitation of food came on, and as the symptoms steadily grew worse he was brought to hospital for treatment

Examination by the x rays showed a coin impacted in the œsophagus at the level of the third rib, the flat surfaces facing anteriorly and posteriorly respectively. On Jan. 1st, 1902, the patient was anæsthetised and an attempt was made to move the coin with the coin catcher. As this effort failed the probang was tried, and on the second attempt the coin was found to be lying free in the pharynx. It was quite black in colour and was entirely covered on one surface with an inflammatory exudation Immediately the coin was removed the patient's breathing, which up till then had been laboured, became easy, and he made a rapid recovery from the anæsthetic As it was not deemed advisable to allow him anything by the mouth, rectal feeding was tried, but the enemata were very imperfectly retained, and as on the *toto* rather more than 42 drachms of bromide of potassium; the bromide was stopped. On Dec. 3rd (thirtieth day) urine was passed naturally. The bowels were very loose and the patient was able to sit up in bed. On the 6th he was allowed bread and milk and custard in place of some of the fluid nourishment. 15 grains of bromide of potassium were given each night. On the 9th (thirty-sixth day) the patient was up for a couple of hours. There was no stiffness remaining except in the legs which were still somewhat rigid. On the 18th he had been up daily and was out on this day for some time. On the 30th the patient was discharged quite recovered.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

### *Adjourned Discussion on Modern Methods of Vaccination and their Scientific Basis.*

A MEETING of this society was held on Jan. 28th, Dr. F. W. PAVY, the President, being in the chair.

Dr. SIDNEY COUPLAND, in opening the adjourned discussion on Modern Methods of Vaccination and their Scientific Basis, said that the Act of 1898 had had a most beneficial effect on vaccination. It had greatly diminished the risk which resulted from vaccinal injury, since by making it obligatory to employ a glycerinated lymph nearly all the infective organisms had been eliminated. The performance of the operation at the child's home instead of at a station had reduced the accidents following vaccination to a minimum. He thought that the profession had not sufficiently considered the slighter injury which followed vaccination In the majority of cases in which bad results followed it was not the lymph which was at fault but some accidental complication. He quite agreed with Dr. T. D. Acland that the Government should have full control of all the vaccine used in the country. With regard to what might be regarded as efficient vaccination he said that since the purified lymph might give rise to such a small amount of scarring the size and area of the scars could no longer be considered as evidence of effective vaccination, and reliance would have to be placed rather on the number of scars than on either their depth or area It was a well-recognised fact that those persons with more scars were better protected than were those with fewer scars With regard to the protective value which a previous attack of small-pox had, he said that out of 250 people who had had small-pox in childhood 10 contracted a second attack of small-pox when exposed to infection, and in an epidemic investigated by Dr. T. D. Savill an even larger proportion occurred—viz., nine out of 41 cases. With regard to the protective value of vaccination, he said that about one in four persons who had been vaccinated in infancy contracted small-pox if exposed to infection in later life. Revaccination conferred absolute immunity, and even in a patient who had had small-pox the immunity could be prolonged by revaccination. In children under 10 years of age who had been vaccinated in infancy the liability to contract small-pox when exposed to infection was one in 12, while in those who were unvaccinated the liability was two in three. He did not consider that all even recently vaccinated persons were absolutely immune owing to their vaccination with various strains of lymph, some of which might have become inert.

Dr. A. E. COPE said that as a public vaccinator he wished to say a few words on the way in which the actual work of vaccination was carried out. He then gave details as to the cleansing of the arm, which he thought in the infant was best carried out with a little rectified spirit, while in revaccination a more thorough cleansing with 1 in 20 carbolic soap was advisable. With regard to the instrument used he was in favour of a platinum lancet with a hard iridium point—this could be sterilised easily in a flame without losing either its temper or its sharpness; it also possessed the further advantage that it did not get the dull, dirty appearance of a steel instrument after being heated in a flame. Before covering up the scratches he waited till an urticarial reaction had taken place and then covered the site of inoculation with a dressing of boric wool. One of the most troublesome complications which he had met with was the chronic eczema which sometimes started around the vaccination scars. He thought that children should be revaccinated at 14 years of age, and that if this were done then the inconvenience of a swollen arm, which often resulted if the vaccination was left till the patient was between 30 and 35 years of age, would be avoided, for the effect would be less severe.

Mr. WILLIAM F. BLAKE asked what constituted successful vaccination. If two persons were vaccinated from the same tube and the one took but the other did not, could it be asserted that the person who did not take was protected against small-pox? He also asked whether it was possible to vaccinate an individual successfully with different strains of lymph within a period of a few months, as had been asserted by a speaker at a former meeting.

Dr. F. CHURCHILL asked if any age-limit could be fixed at which it was unnecessary to revaccinate adults. He had been in the habit of advising revaccination in persons even of advanced age.

Dr. BERNARD O'CONNOR said that he thought that revaccination should be performed at 14 years of age and that after that revaccination should be performed at fixed periods until the individual ceased to take.

Dr. F. ST. GEORGE MIVART said that he had seen keloid occur after vaccination and that this had occurred in certain districts. He had been unable to discover any cause for this condition.

Dr. S. MONCKTON COPEMAN, in reply, said that the effect of glycerine in the lymph was to inhibit and eliminate all the non-spore-bearing organisms, and since most of the pathogenic organisms were non-spore-bearing the lymph was thus freed from all infective organisms. Even if such organisms as those of erysipelas and tubercle were intentionally added to the lymph in considerable quantities the subsequent addition of glycerine gradually eliminated them, so that after a given interval the lymph was free from any such infective qualities. He considered that the same amount of vaccination was necessary in the child as in the adult, and, as a rule, the vesiculation was less severe in relation to the amount of vaccine used in the child than in the adult. He said that no satisfactory method of standardising lymph had yet been discovered. There was no doubt that a person might contract small-pox twice or even three times. He referred to the great immunity which vaccination gave, and as an instance said that he had on two occasions accidentally inoculated himself from cases of confluent small-pox, with the result that no infection took place. With regard to inert lymph he said that when it was suspected that a vaccination had failed because of inert lymph the patient should not at once be revaccinated but should wait a month, for a certain amount of local immunity seemed to be produced even by apparently inert lymph. It was generally assumed that the glycerinated lymph was less potent than was the older form of lymph. This he did not think was the case, for in the preparation of the calf lymph the epithelium in which the vaccine organisms were supposed to be was scraped off, whereas in the lymph taken from the vesicles only the fluid portion was taken. In conclusion, he referred to the possibility of vaccination by internal administration.

## MEDICAL SOCIETY OF LONDON.

### *Discussion on the Nature and Treatment of Obesity.*

A MEETING of this society was held on Jan. 27th, Dr W. H. ALLCHIN, the President, being in the chair.

Sir T. LAUDER BRUNTON opened a discussion on the Nature and Treatment of Obesity. He said that it was difficult to give an exact definition of obesity, but in general terms it might be said that obesity commenced when the patient's fat was obviously very much greater than normal or when it became inconvenient to himself. In order to define more accurately what he meant he gave the following figures. The average height of an Englishman was about five feet eight inches and his weight 11 stones. This remained pretty constant till the age of 40 years, when the weight generally began slightly to increase. According to van Noorden this weight might increase as much as 15 per cent. and still be within the normal limit. When it reached 30 per cent. the person was regarded as stout; from 30 per cent. to 35 per cent. as

During the first 24 hours the temperature rose to 101° F. and the pulse increased in proportion; the child was rather weak and restless. After this there was marked improvement, both temperature and pulse remaining normal except on the 20th, 21st, and 22nd, when there was a slight rise due to the child cutting a tooth. There was no vomiting; the bowels were opened naturally on the first day and regularly afterwards. During the first day small quantities of meat peptones and hot water were given by the mouth, and saline enemata; afterwards the meat peptones were continued and peptonised milk was given. On the 18th the wound was dressed; it looked very well and some of the stitches were removed. On the 25th the rest of the stitches were taken out and the wound was quite healed. The child went to the convalescent home on July 4th.

*Remarks by* MR. ROBINSON.—Umbilical polypi are not infrequently met with on the site of the separated cord. Although sometimes in the past loosely spoken of as granulomata they rarely are so histologically. The majority show an adenomatous structure consisting of large Lieberkühn's crypts with goblet cells or of glands branched like those about the pyloric end of the stomach. Such a histological appearance suggests its origin—viz., from one of the epithelial-lined tracts in the cord; these are two in number, the omphalo mesenteric duct and the urachus.

In normal development the omphalo-mesenteric duct atrophies from the small intestine to the abdominal wall, setting free the bowel, and as a rule leaves behind no evidence of the site of its original attachment to the bowel. The commonest variation, probably, is for its central part to remain patent as Meckel's diverticulum, but it may, as in the present case, remain patent in its whole length. In other instances the lumen becomes obliterated and there will remain a ligamentous cord stretching from the bowel to the navel; the latter cord may again lose its connexion with the abdominal wall, remaining free or becoming abnormally adherent especially to the mesentery. These variations may, as is well known, play an important part in inducing different forms of intestinal obstruction. The urachus is the continuation of the bladder to the umbilical cord and related to the allantoic outgrowth from the hind-gut.

The histology of the polyp points to its origin from intestine, as in the recorded cases there is no account of one being composed of cells resembling those of the bladder; in this connexion, however, it must be borne in mind that a transition has here occurred from that resembling the lining of the hind-gut.

In nearly every case of a polyp the child is brought to the hospital with a history of discharge from the navel, and on examination the little raspberry-like growth is seen. It behoves the surgeon to examine every such case, most carefully inquiring as to, and seeing the character of, the discharge and looking for any lumen in the growth. When the discharge resembles the contents of the small intestine it is evident that there is a patent duct, the polyp in this instance being the prolapsed mucous membrane. Having, then, established the existence of such a patency the surgeon must consider his position as to how and when to act. As to the former there can be no two opinions bearing in mind the serious complications which may arise from non-interference. The prospect of strangulation under or across the band must always loom largely before the surgeon until this has been made impossible by an operation. The surgeon must be guided when to act by the child's general condition and also by the amount of discharge from the opening. If this is small it may be assumed that the lumen of the duct is narrow and that, if the operation is postponed, no great developmental disproportion will ensue in the lumina of the two ends of the bowel; but if the discharge is free and what comes from the rectum is limited then he must bear in mind that there will probably be a disproportion in size which will be more marked the longer the operation is postponed.

As to the surgical technique employed in this case no further remarks are necessary, the general principles in vogue in abdominal surgery being adopted.

The literature of this subject is extremely scanty. Treves[1] reports having successfully performed a plastic operation for the closure of the abnormal passage in a male infant a few weeks old, but he gives no details as to what that operation was. Beyond this case I can find no other recorded where such a plastic operation was deliberately done. From my search several cases have been reported where in an operation for intestinal obstruction a band has been found, the remains of the duct with only its central part patent—a Meckel's diverticulum with a fibrous cord passing to the navel—in these the diverticulum and its continuation have been removed.

## ROYAL ISLE OF WIGHT COUNTY HOSPITAL.

### A CASE OF TRAUMATIC TETANUS; RECOVERY.

(Under the care of Mr. F. J. WADHAM.)

THE value of antitoxin in the treatment of tetanus requires very careful examination. Numerous reports are published describing cases in which its administration has been followed by recovery, and a smaller number of cases in which death has resulted. Yet it must not be imagined that the numbers of the recorded cases represent the relative frequency of recovery and death after treatment with antitoxic serum. Before the introduction of the antitoxin a proportion, by no means small, of the cases of tetanus recovered, though statistics vary greatly as to the exact proportion, and it has not been definitely shown that the percentage of recoveries has been materially altered. In the present state of our knowledge the administration of the antitoxin should not preclude the use of other means which have been found useful, such as the bromides. It would be well if we could obtain a long series of cases which had been treated in one institution both before and after the introduction of the antitoxin. We should then be in a better position to judge of its value. For the notes of the case we are indebted to Dr. R. O. H. Kennedy, house surgeon.

On Nov. 3rd, 1901, a man, aged 22 years, a groom, whilst working in a stable broke a pane of glass in the window and in so doing cut his right index finger on the dorsal surface of the proximal phalanx. He stated that the wound bled profusely and that in order to check the hæmorrhage he placed some cobweb on it. He did not suffer much pain. The wound suppurated slightly and then after a few days it closed up. On the 14th he felt some stiffness in his jaws and at dinner had difficulty in masticating his food and in swallowing. The wound broke down and he suffered some pain in it. On the 15th he consulted Mr. Wadham who immediately sent him to the Royal Isle of Wight County Hospital. He complained of pain and stiffness in the back and neck. Considerable trismus and risus sardonicus were present. The wound, which was about three-quarters of an inch long, was unhealthy-looking and discharging sanious pus. He was placed in a darkened room and put on bromide of potassium (30 grains every four hours), brandy (10 drachms every four hours), and beef-tea and milk (four ounces every two hours alternately). The wound was washed in a solution of perchloride of mercury (1 in 1000) and was dressed with a pad of gauze wrung out of a solution of the same strength. The axillary temperature was 98.6° F., the pulse was 60, and the respirations were 20. During the day the patient became very restless and all the tetanic symptoms became more marked. 10 cubic centimetres of anti-tetanic serum were injected into the flank. The spasms now appeared to be more clonic in character than tonic, with exacerbations. The injection of serum was continued during the first seven days until 110 cubic centimetres had been given, not more than 10 cubic centimetres being given at any one time. The various symptoms increased in severity till the fifth day after admission, when almost absolute trismus was present, swallowing was difficult, and great opisthotonos and pain in the back and neck with exacerbation were caused by the slightest noise or movement. The passage of a catheter, which had been necessary since the second day, became very difficult owing to the spasm which it caused. Nitrite of amyl was now administered as an inhalation during the exacerbations and afforded marked relief.

The patient remained in this condition till Nov. 24th (twenty-first day after injury), when the exacerbations became less severe and less frequent, and diuresis became much increased. On the 26th (twenty-third day) an enema was given, the bowels not having been opened since admission. On the 28th bromism developed, the patient having taken in cases of anorexia nervosa patients wasted quite out of proportion to the quantity of food which they took. He believed that there was in obesity a "perversion of metabolism."—Sir T. LAUDER BRUNTON replied.

---

[1] Intestinal Obstruction, 1899, p. 42.

## CLINICAL SOCIETY OF LONDON.

### *Exhibition of Cases.*

A MEETING of this society was held on Jan. 24th, Mr. HOWARD MARSH, the President, being in the chair.

Dr. SEYMOUR TAYLOR showed a lad, aged 15 years, with Bilateral Facial Palsy. He had "paralysis of the legs and arms when five years old," from which he recovered. He had never been able "to move his face." There was no history of delivery by forceps or of otorrhœa, but he had had two attacks of rheumatic fever followed by valvular disease. The lad exhibited almost complete bilateral facial palsy; but there was slight voluntary power in the risorius and the depressor anguli oris, and also in a few fibres of the orbicularis oris muscles. He talked readily, but all labial and explosive consonants were pronounced by the aid of the tongue, so that "apple" was turned into "attle," "pear" became "tear," and so on. There was no sign of degenerative changes in any other nerve. The exact seat of the lesion had not yet been determined by complete electrical reactions, but the probability was in favour of the lesion being peripheral.—Dr. F. E. BATTEN suggested that the case might be a myopathy of the Landouzy-Déjerine type in which the face only was involved.

Mr. G. TURNER showed a case of Actinomycosis which had been cured by 45-grain doses of potassium iodide administered three times a day. The case was fully reported in the Transactions of the Clinical Society of London, vol. xxxiii.—The PRESIDENT referred to a case of actinomycosis of the buttock which he had treated in the same way with complete success.

Mr. LAWRIE H. MCGAVIN showed a girl, aged 18 years, with Bilateral Cervical Ribs and an Abnormal Bony Mass at the First Chondro-sternal Junction. She noticed a mass under the left clavicle six months previously, which had given rise to no inconvenience except from time to time aching pains in the region. On examining her the condition of the neck was accidentally discovered. She had lately complained of slight numbness and tingling over the dorsum of the first and second metacarpal bones of both hands. In addition to this she had occasionally experienced shooting pain in the area of distribution of the superficial branches of the cervical plexus, especially of the great occipital and supra-acromial divisions. The symptoms were more marked on the left than on the right side. The position of the supernumerary ribs was demonstrated on a skiagram; that on the right side was short and straight, and ended over the centre of the first rib, springing from the transverse process of the seventh cervical vertebra. That on the left was curved, arose from the same point, and appeared to end much nearer to the inner side of the clavicle. The sternal extremities of the first ribs were markedly different in shape, that on the right being broad and thick, while that on the left was thin and indistinct. At the upper margin of the skiagram was seen an indistinct nodular bony mass, apparently in connexion with the transverse processes of the fourth and fifth cervical vertebræ.—Dr. SEYMOUR TAYLOR said that these accessory ribs generally occurred in women and on the left side. He regarded them as a reversion of type.

Mr. J. JACKSON CLARKE showed a female child, aged nine years, with an Abnormal Curvature of the Spine determined by Shortening of the Left Rectus Abdominis Muscle. The patient's breathing was purely abdominal and the abnormal curves in the spine were fixed, not disappearing either when the patient lay down or when manual pressure was employed. On attempting to straighten the spine he observed that the lower portion of the thoracic wall on the left side was dragged upon, that the left rectus muscle was tense and hard in every position of the body, and that it was less resistant when the patient was sitting with the body bent forward than it was when she lay down on the back. On inquiry he found that when the patient was six months old her mother had noticed that the right side of the abdomen was more prominent than the left. The case was probably akin to the common form of wry-neck due to organic shortening (contracture) of one sterno-mastoid in infants. The treatment had been instrumental and gymnastic. Improvement had been thus obtained through the stretching of the shortened rectus; it remained to be decided whether any marked gain would result from elongation of the left rectus by the simple plastic operation by Z-shaped incision. There was no abnormal reflex. In the absence of progressive myositis, &c., he concluded that the origin was congenital.—Mr. A. H. TUBBY asked if the condition was congenital or acquired and whether any reflex cause for the spasms of the muscle had been found.—Mr. MCGAVIN asked if there had been any traumatism at birth.

Mr. W. D. HARMER showed a man, aged 20 years, with Arthropathy of the Shoulder-joint in a case of Syringomyelia. The patient had sustained an injury to the left shoulder 12 months previously, followed by a swelling (? ruptured muscle), which gradually subsided. Eight months ago a painless swelling of the same joint occurred, commencing suddenly without injury. This was followed by two months' grating and "shifting of bone." The back had been curved for the last three or four years. There was no history of syphilis. The patient was short and was strongly built. There was no muscular wasting. The left shoulder-joint was uniformly enlarged. Movement was free as high as the level of the acromion process, but was attended with marked grating and luxation. When the arms were hanging there was an inch of lengthening of the left arm, due to the laxity of the ligaments. There were well-marked kyphosis and lateral curvature with convexity to the left. There had been numerous painless ulcers on the thumb and fingers of the left hand, commencing as bullæ. There was complete thermo-anæsthesia from about the fifth cervical to the third lumbar spines, including the arms. Analgesia was marked only over the front and the lateral aspect of the shoulder-joint; it was slight in the left hand. Tactile sense was normal. There was no loss of muscular pressure or of localisation senses. The knee-jerks were marked. There was no ankle-clonus. Nystagmus had been observed.—Mr. J. R. LUNN referred to a similar case in a man, aged 52 years, who had been under his observation for 10 years. This case was fully reported in vol. xxvii. of the Society's Transactions.

Mr. TUBBY and Dr. J. PURVES STEWART showed a case illustrating a New Method of Treating Old-standing Paralysis of the Upper Root of the Brachial Plexus. The patient, a man, aged 57 years, fell on to his shoulder and head two years ago. He was unconscious for an hour afterwards and on recovery was unable to use his left arm. After treatment at various hospitals without benefit he was admitted to Westminster Hospital under the care of Dr. W. Murrell. There were then marked paralysis and atrophy about the left shoulder and upper arm, and Dr. Purves Stewart reported total loss of electrical excitability in the deltoid, infraspinatus, biceps, brachialis anticus, and supinator longus on the left side, and consequent inability to adduct the arm or to flex the elbow. There was also some anæsthesia along the outer side of the upper arm and forearm, which subsequently disappeared. These symptoms pointed to a paralysis of the upper root of the brachial plexus of the Erb-Duchenne type. Mr. Tubby, 20 months after the accident, transferred part of the triceps and fixed it into the biceps with the object of restoring the power of flexion at the elbow, and a month later an attempt was made to restore power to the deltoid. Since the operation the transplanted portions of muscle had been assiduously massaged and the faradic current had been applied. There had been great improvement in the movements and in the utility of the limb. The patient could flex the elbow fairly and during flexion the transplanted part of the triceps could be felt in front of the elbow, and both galvanic and faradic excitability had returned. He had not yet recovered the power of abducting the arm, but the transplanted part of the pectoralis major could also be felt to harden. At first there was a total loss of excitability both to induction shocks and to the galvanic current. Three months after operation the galvanic excitability returned and six months after faradic reaction could be demonstrated.

Mr. HAROLD L. BARNARD showed a child who had come under his observation with the characteristic signs of Coxa Vara. On questioning the mother he found that 18 months before the child had complained of pain in the hip and for three days had been unable to walk at all. Then he began to walk again, but the following year he commenced to limp. The signs were definitely those of coxa vara—viz., abduction was very much limited, internal rotation also very too stout; from 35 per cent. to 50 per cent. as moderately obese; and above 50 per cent. as very obese. The accumulation of fat occurred specially in the subcutaneous tissue, in the omentum, and around the heart and kidneys. Fat consisted chiefly of mixtures of different proportions of glycerine united with fatty acids. These mixtures varied in different animals, but each animal kept its own fat nearly up to a constant standard, although it might feed on other animals having a different kind of fat. This was not altogether the case, however, for as an old nurse of Weir Mitchell remarked, "Some fats are fast, some fats are fleeting, but cod-liver oil fat is soon wasted." This had been proved scientifically, for in animals fed on rape seed oil this oil could be detected unaltered in the tissues. Accumulation of fat in man depended on, firstly, how much fat or fat-forming food was taken into the body, and, secondly, on too little being burned off. These two causes might act together. Fat was, however, formed from different kinds of food even if fat itself was not contained in them, such as albuminates and carbohydrates. The body was able to split off fat with difficulty from albuminous materials, such as lean meat, but it formed fat with considerable ease from sugar and starch. The tendency to lay on fat was therefore determined to a considerable extent by the nature of the food. The tendency to the accumulation of fat both in men and animals after the removal of the testes and ovaries was well known, and Loewy and Richter found that in dogs the administration of ovarian extract had no effect when the generative glands were present, but increased oxidation in animals from which the ovaries and testicles had been removed. It was usual to distinguish two forms of obesity, the plethoric and anæmic. He referred to an instance of the former in which the patient had successfully effected a reduction in his weight so that he could run and vault with ease, but he found that when his bodily activity increased his mental activity diminished. The anæmic type of obesity was most frequently found in women. Certain diseases which lessened activity tended to cause the accumulation of fat, such as chronic nephritis, on account of the languor which it produced. With regard to the treatment of obesity, as the cause of the condition either in its severe or slight forms consisted in the ingestion of more fat-making food than the body could burn off, its treatment naturally consisted in limiting the food both in quantity and in quality and increasing the combustion of the body by accelerating the circulation. The best way of stimulating combustion was undoubtedly muscular exercise, but in severe cases the difficulty was that patients were unable to take muscular exercise, and in these cases the use of massage by means of which the circulation through the muscles might be increased threefold, tissue change was obtained without inconvenience to the patient. Massage alone was not sufficient and should only be the preliminary to more active exercise, and even exercise alone was rarely sufficient to bring down obesity. It was necessary that the amount of food should be lessened and this could generally be done by insisting that solids and liquids should be taken at different times. Many people were apt to wash down food, and especially farinaceous food, without much mastication; but if the farinaceous food was of a dry kind, such as crisp toast, rusk, or biscuit, the quantity that could be got down in a given time if fluid was withheld became very much less. He suggested that digestion in the stomach had less tendency to form fat than when the digestive process was carried on in the intestine. Should the regulation of diet combined with a fair amount of exercise fail to reduce the patient then the next best thing was to put the patient on the so called "Salisbury" treatment, which closely resembled that recommended by Harvey and Banting with the addition of hot water. The disadvantage of the Banting treatment was that an excessive amount of nitrogenous waste product occurred which unless eliminated produced poisonous results. The use of thyroid extract increased tissue change and would reduce fat considerably, but in most cases it was far better to diminish obesity by attention to feeding and exercise than by the use of thyroid. Nervousness, tachycardia, and tremor were produced by taking thyroid for too long a period.

Dr. I. BURNEY YEO said that he thought obesity might be divided into two classes—those cases that were easy to treat and those that were difficult to treat. In those which arose from dietetic errors the treatment was easy, while in those due to a "vice of metabolism" or of hereditary nature the carbohydrates might be removed with but little benefit. It was of great importance that treatment should be begun early. If a man at the age of 40 years began to show signs of obesity he should leave off sugar and should eat less bread and less potatoes. He referred to the successes that had been obtained by limiting the patient to an absolute milk diet of one quart per diem, but in such cases the patient must be kept at absolute rest. He considered that it was disadvantageous to limit obese persons too closely in the amount of water which they took, for many of these patients were of gouty nature and needed the water to eliminate the waste products. He referred to the effect of castration and doubted whether internal secretion played so important a part as was generally supposed, and suggested that the loss of sexual emotions accounted for the increase of obesity. He thought that thyroid extract should only be given in those cases which did not react to other forms of treatment. He considered that alcohol was an important element in the production of obesity. He was of opinion that the Salisbury treatment was risky in its application to elderly people.

Dr. SCHOTT (Nauheim) said that he intended to confine his remarks to the fatty condition of the heart. He described three forms: firstly, that in which fat surrounded the heart; secondly, that in which the fat was between the muscle fibres of the heart; and thirdly, that in which there was fatty degeneration of the muscular fibres. Treatment might be carried out by two methods: firstly by drugs and secondly by diet and exercise. With regard to the former he said that not long ago it was the habit to use purgative waters, so that the patients rapidly lost weight. In young persons with good muscular systems this might be carried out successfully, but in anæmic and old persons it was attended by very considerable risk, and he mentioned two cases in which patients lost 54 and 45 pounds respectively in a few weeks and fatty degeneration of the cardiac muscle took place from which the patient some six months later died. If fat was lost rapidly it was lost not only in the subcutaneous tissue but also in the nerves, the brain, and the muscle. It was often difficult to get stout persons to overcome their apathy and to take exercise. He considered that cool effervescing baths were safer and better for obese persons than Turkish baths, and he had seen serious collapse result in the latter. He characterised the treatment by milk alone and also that by dry rolls as a "hunger cure." Great care was necessary not to reduce the fat too rapidly.

Dr. R. HUTCHISON suggested that the reason why certain persons tended to get fat was that they were more economical machines and radiated less heat. He said that the theory lacked experimental verification. Treatment of obesity should be by oxidation of the fat in the body, and this was possible by the administration of thyroid extract. Unfortunately, however, it also produced oxidation of the albuminoid bodies and therefore largely increased the excretory products. With regard to the restriction in the quantity of fluid he said that the simple limitation of the amount did not experimentally produce a diminution of weight, but that the result was due to the smaller quantity of food that could be conveniently taken. In Germany, however, where the fluid commonly taken was beer, the restriction might have a marked effect.

Mr. C. R. B. KEETLEY referred to the disappearance of umbilical hernia under the Banting diet and he said that he frequently gave a modified diet before operating for the radical cure of such herniæ. He suggested that in some cases the fat on the abdomen might be removed by operation.

Dr. A. P. LUFF said that it was important to distinguish between obesity which was inherited and that which was acquired, and they should not be treated by one and the same method. He thought that the Salisbury treatment should not be attempted in any case in which there was either renal disease or weakness of the heart. He quite agreed with former speakers as to the advantage of allowing no water with the meals. He considered that thyroid extract should not be administered in persons with any affection of the heart or kidney, but that in other cases it was of service.

The PRESIDENT referred to the uncertainty of the causes of obesity; in some cases it followed on an excess of food, while other individuals got fat on but a very small amount of food. Again, there were individuals who took a large amount of food and yet remained small and thin. That the nervous system had a marked influence was shown by the fact that mentally deficient children often became very fat and also by the abnormal production of fat in the condition known as "adiposa dolorosa"; on the other hand, in the on Dysentery in South Africa, and of contributions by members unable to be present, were distributed in the room.

After a *résumé* by Dr. Mott of the salient points in his paper a contribution from Dr. P. J. Baily was read by the Secretary, in which, after describing the symptoms of the disease in his own case, he gave an account of a succession of outbreaks at Hanwell Asylum during the past two years. 15 of the staff were attacked but none fatally, whereas among the inmates 13 in 48, or 27 per cent., of the males, and 9 in 47, or 19 per cent., of the females, died, the majority of the deaths among both sexes being those of general paralytics or of persons who were 70 years of age. A large proportion of the cases in 1901 were of persons, including one of the staff, who had suffered previously, and the infectious nature of the disease was well seen in a mild outbreak in a female ward last April, as was the value of prompt removal of the cases to isolation wards when circumstances permitted of its being carried out.

A short communication was read from Dr. Claye Shaw in which, while admitting that the disease as described by Dr. Mott differed in no respect from tropical or camp dysenteries, he maintained that there was an asylum dysentery distinct from dysentery in asylums, not bacterial and of extrinsic origin, but induced by degeneration and necrosis of the intestinal tissues dependent on the nerve changes inseparable from the general paralysis and like degenerations in the chronic insane, and that the cases that he had described as having occurred under his care at Banstead Asylum belonged to this class, arising from time to time independently of faulty sanitation or nursing and often more or less anomalous in their phenomena.

Colonel Kenneth McLeod, R.A.M.C., said that his first experience of dysentery was at the Durham County Asylum in 1864, a like outbreak occurring at the same time in the asylum at Carlisle, when he was much impressed by a paper by Dr. T. S. Clouston on Sewage Exhalation as a Cause of Dysentery, which, though now 50 years old, was still well deserving of study. Among 200 inmates there were 30 cases, 20 of which were fatal, occurring in small groups at short intervals between March and August, and one in the following March, ordinary diarrhœa prevailing at the same time and a few cases of enteric fever. No fault could be found with the food or the water, but the excreta were received in a huge cesspit and from time to time the putrid sewage was spread over a meadow. The cases, 24 of which were on the ground floor, always occurred from three to six days after such irrigation, provided the wind was blowing from that direction, except those in March, 1865, which followed a stoppage and opening up of the drain. One attendant and a labourer were also attacked. The like coincidence of the outbreaks with irrigation was observed at Carlisle, where the sewage tank was not covered as it was at Durham, confirming Dr. Clouston's view of its connexion with sewage exhalations, though the inmates might have contracted the diseases while engaged in the work of irrigation. He had seen much dysentery in India in jails, asylums, and hospitals, and among the general population, and latterly at Netley among men invalided from all parts of the world. In India it was always associated with overcrowding, insanitary conditions, and foul water-supply. In Calcutta the diphtheritic and worst form was very frequent, but wherever the new public service of pure water was substituted for that from the tanks used for bathing, &c., dysentery and other fæcal diseases were greatly reduced or ceased altogether. The dysentery which he had seen at Durham differed in no respect from that of India. The relations between dysentery and enteric fever, sometimes one and sometimes the other preceding, called for investigation, as did the persistence of dysentery in asylums when the general population, though amid more insanitary conditions, escaped. The insane were doubtless more susceptible from their want of decency and from their uncleanly habits, and less resistant from their lower vitality. Major Buchanan had described the "terminal dysentery" that carried off many phthisical patients and perhaps the majority of lepers. He deprecated the use of euphemisms as "ulcerative colitis" for what was simply dysentery and insisted on its essentially fæcal causation and preventability.

Dr. E. W. Goodall criticised Dr. Claye Shaw's paper, whose remarks as to the non-occurrence of primary cases among the attendants in asylums might equally be applied to so obviously infectious a disease as diphtheria in hospitals, and he failed to see the "mystery" that Dr. Shaw found in asylum dysentery. He had at the Eastern Hospital, Homerton, a young woman who when convalescing from enteric fever died from "ulcerative colitis" or dysentery. He knew that some unreported cases of dysentery had occurred at Leavesden Asylum several years ago, and that in 1895 there were numerous cases of fatal diarrhœa. Some of these were very probably enteric fever, but the others were very obscure, and in none of the fatal cases was ulceration of the colon observed. Dr. A. Shadwell had suspected the water-supply. How, he asked, could the appearance of dysentery in asylums be accounted for when there was none outside?

After some remarks by Mr. Shirley Murphy and Dr. W. H. Hamer, Dr. Stansfield, in reply to Dr. Goodall's question, said that patients were constantly transferred from one asylum to another, and that the new asylums were at once filled by drafts from the older and overcrowded ones, many of the patients suffering from chronic or latent forms of the disease. He had thus had many cases at the County Asylum, Bexley, within the first three years, the initial cases in each outbreak having always been transfers, while the sanitary conditions of the asylum were perfect.

Dr. Eric France held that no one with any experience of dysentery in asylums could doubt its specially infectious character. At Claybury Asylum after isolation was carried out the cases were far less numerous and the mortality only half as high as before, though perhaps the recognition of its infectivity by the attendants had as much to do with the improvement. Under ordinary circumstances he did not think that more isolation was necessary than was required with enteric fever, but the conditions of the insane in asylums were not ordinary owing to their filthy habits.

Dr. Wilson said that a patient having been admitted into the hospital at Trinidad from the gaol where dysentery prevailed communicated the disease to those in the bed on each side and to two others in the same ward.

Dr. Washbourn then read a paper by himself and Mr. Owen Richards on South African Dysentery and its Relation to that in Asylums, in which they described three types of the disease alike marked by bloody and mucous stools, fever, tenesmus, and abdominal pain in different degrees. The normal type, with its febrile stage lasting a week, the temperature ranging between 101° F. in the morning and 104° in the evening, and thick white fur on the tongue, the symptoms subsiding in a week or becoming chronic unless death occurred in the first week from the fever itself or subsequently from perforation, peritonitis, or exhaustion. The second type comprised mild non-febrile cases soon recovering, and the third was distinguished by the pyrexia continued for three or four weeks, with perhaps an entire absence of blood and mucus, the bowels being either loose or constipated. These cases were often taken for enteric fever, but were doubtless due, like the typhoid form of scarlet fever, to secondary septic invasion. The mortality in South Africa had been low, the patients being healthy young men—only 1·86 per cent. in the Imperial Yeomanry Hospital at Pretoria. Liver abscess was rare and in one case the pus was full of streptococci and bacilli, thus differing from the usual tropical form. The cæcum and rectum were most affected, the lesions being thickening of the walls with hæmorrhages and ulceration, and perforation being the most frequent cause of death. There were no amœbæ in the contents of the intestine or of the abscesses.

Dr. H. D. Rolleston, who succeeded Dr. Washbourn at Pretoria, said that in the absence of amœbæ and of the sterile abscesses of tropical dysentery these cases corresponded to those described by Shiga in Japan. In his sections the inflammation appeared to have begun in the mucous, and not, as Dr. Mott maintained, in the submucous, layers, which might point to a different causation though the clinical phenomena were the same.

Dr. Washbourn then read a communication from Dr. T. Dunlop, describing an Outbreak of Dysentery at Aldershot in August and September last. It had never been known in the district before, but the diagnosis was confirmed at once by Dr. Washbourn, Lieutenant-Colonel Franklin, R.A.M.C., Dr. Donald of Uganda, and others. There was diarrhœa, followed by blood and mucus, and great tenesmus, but not much fever or pain. The cases were 170 or 180, with 38 deaths, about 27 per cent., 28 of these being of children under five years of age. Its infectivity was very marked. No cause could be detected, the most insanitary quarter of the town escaped, and the water-supply was the same as was that of the camp where one case only occurred.

Mr. E. J. F. Hardenberg described 19 cases in the same outbreak that had been under his care, of which limited, while flexion and adduction were free No pain was complained of in the joint or on movement The treatment *so far had been a Thomas's knee-splint to keep the* weight off the hip-joint, the mother objecting to any operation. The child had suffered from blood-spitting.—Mr. JACKSON CLARKE thought that no operation should be performed in these cases before the bone had become fully developed and that most cases did well with massage and exercises.—Mr. A. A. BOWLBY suggested that the condition coxa vara was often evidence of slight tuberculous affection of the hip-joint. He asked if there was either shortening or muscular wasting in this case, and if these were present he thought that the condition was probably tuberculous. There was no evidence of rickets in the case.—Mr. TUBBY thought *that there was often considerable difficulty in distinguishing* coxa vara from congenital dislocation of the hip.—Mr. BARNARD, in reply, said that he considered that neither wasting nor shortening was necessarily evidence of tuberculous disease of the hip.

Mr. BARNARD also showed a patient who had Compound Fracture of the *Patella* *This he had sutured with kangaroo* tendon; suppuration followed and drainage of the knee-joint, bony union and good movement resulting.

Mr. J. HUTCHINSON, jun, showed a lad, aged 17 years, with Traumatic Separation of the Epiphysis of the Head of the Femur demonstrated by skiagraphy. The patient had had a fall, with probably forced extension and eversion of the right hip. He was unable to walk and complained of intense pain on passive movement of the right thigh. The latter was everted, as in most cases of impacted fracture of the femoral neck. There was no bruising over the trochanter or abnormal fulness in Scarpa's triangle. *The right ilio-tibial band was slightly* relaxed, but yet no shortening could be made out. Pressure on the trochanter did not cause pain. The Roentgen rays showed very plainly a separation of the femoral head exactly at the epiphyseal line, the epiphysis remaining in the acetabulum and being only in contact with the femoral neck *to about half the normal extent. Under an anæsthetic the* limb could be freely moved in all directions and a faint sort of crepitus was obtained. The eversion could easily be overcome, but when the extension was taken off the deformity at once recurred. The limb was put on a Liston's long splint and almost perfect apposition was obtained. Until the intro*duction of the x rays positive evidence as to the occurrence* of traumatic separation of this epiphysis was singularly scanty.—Mr. BARNARD said that it had been shown by Royle Whitman that cases of this nature which occurred before the age of six years were usually fractures, whereas in the older patients they were usually cases of separation *of the epiphysis.*

Dr. W. EWART showed a patient with Major Dilatation of the Left Auricle. The distinctive physical signs were:—1. *Palpatory:* the definite systolic pulsations in the right mammary region, and the occasional thrill perceived there as well as at the apex, and the occasional pulsation of the liver. 2. *Auscultatory:* the identical character of the murmurs in both mammary regions, whilst in the interval between them and at the aortic interspace the systolic murmur, though easily perceptible, was much less loud; and the presystolic murmur, which, however, in this case was of inconstant character. 3 *Percussory* · the tracings exhibited showed the conditions which served as a basis for the diagnosis. *Anteriorly* the cardiac dulness was much enlarged in its transverse diameter and somewhat also in its vertical diameter, the liver being depressed as well as slightly enlarged, whilst at the base there was no dulness suggestive of an aneurysm. The left cardiac boundary, although further out than normal, presented no irregularity, and the right boundary did not differ much from that of a greatly enlarged right auricle. But *posteriorly* the dulness was characteristic. The dulness belonging to the heart was slightly enlarged, but that special to the left auricle was considerably increased (from a normal size of about two and a half inches by two inches to that of nearly four inches by two and *a half inches*) mainly *in its* transverse diameter and in the direction of the seat of abnormal pulsation, which by auscultation was identified as belonging to the left auricle

Mr. ARTHUR E. J. BARKER showed a case of Excision of the Cæcum. The patient was a man, aged 30 years, who was operated on for acute *intestinal obstruction on May 7th*, 1899. The enormously distended and hypertrophied small intestine was first incised and five pints of liquid fæces were evacuated. The cause of the obstruction could then be made out to be a hard growth round the ileo-cæcal valve. The small gut, at about two feet from its termination, was therefore anastomosed laterally with the transverse colon. Six weeks later a fresh incision was made over the cæcum and the latter was excised with some inches of the ascending colon and ileum. Beyond the presence of a slight fæcal fistula for some weeks, recovery was perfect. The patient was now in excellent health, without any evidence of recurrence, two years and eight months after operation. The growth was a typical carcinoma.

Mr. BARKER also showed a case of Excision of the Transverse Colon in a woman, aged 58 years, who was operated on for carcinoma of the transverse colon and chronic obstruction *on Oct. 25th, 1900.* She was suffering at the time from long-standing diabetes. About four and a half to five inches of the transverse colon were removed and end-to-end anastomosis followed. The dressings remained untouched for 10 days. On their removal a small fæcal fistula was found, which discharged for some weeks. Recovery was otherwise uneventful. *The growth was typical carcinoma.* The patient had been in first-rate health ever since, and showed no evidence of recurrence.

Dr. NORMAN DALTON showed a case of Ataxic Paraplegia in a man, aged 53 years, who contracted syphilis two years previously. His present symptoms had been coming on about one year ago. His mind was sound, but he was emotional and excitable. His symptoms were partly those of locomotor ataxy and partly those of lateral sclerosis. The eyes and the upper limbs were normal. As a rule he stood fairly steadily with his eyes shut. He complained of "precipitate" micturition and defecation. In "walking" he brought his *foot down forcibly on the heel as in ataxia, but he did not* lift the knees and the legs were affected by a certain amount of stiffness The muscles of the legs and thighs were rather flaccid. The electrical reactions were normal. The "knee-jerks" were greatly exaggerated, particularly on the left side, and ankle-clonus could be obtained always in the left *foot. The plantar reflex* was of the *extensor type.* There was no delayed sensation. He had complained of pains in the left leg, shooting from the hip to the foot, sometimes accompanied by twitching movements. In the right lower limb as high as the crest of the ilium (back and front), there was loss of painful sensation and of sensations of heat and *cold.* The sense of touch was retained and the sole of the foot was very sensitive to touch.. There was no loss of the sense of position of the lower limbs. There had been no definite crisis, but he had had pains in the hypogastrium.

Dr. W ESSEX WYNTER showed a case of Congenital Spinal Degeneration with Symmetrical Arthropathy in a young man, aged 17 years, who was kicked over the left eye by a horse at 14 years of age Two years ago difficulty was experienced in walking, then it was noticed that the right hip was stiff. In May, 1901, the left hip was similarly affected, and by June there appeared to be no movement at all in either. On admission to hospital on Dec. 9th, 1901, both hips were completely fixed in a fully-extended position. There was some enlargement on the right trochanter. Measurement from the anterior superior spine to the internal malleolus was 33½ inches on both sides. Both trochanters were below Nélaton's line. Bryant's line: left, two and three-eighths inches; right, two and five eighths inches. There was no wasting or loss of sensation or of muscular power. Electrical reactions were normal. The reflexes were uniformly exaggerated. The patient stood in a peculiar attitude, with the knees slightly flexed and the spine curved forward. He walked by rotating the pelvis and spine After 14 days' treatment by iodide of mercury there was some movement in the left hip The urine and the temperature were normal.

---

## EPIDEMIOLOGICAL SOCIETY.

### *Dysentery in Asylums.*

A MEETING of this society was held on Jan 17th, Dr. PATRICK MANSON, C M.G., F.R.S, the President, being in the chair.

The meeting was devoted to a discussion of the paper read on Dec. 13th, 1901, by Dr. F. W. MOTT on Asylum Dysentery, a short extract of which appeared in THE LANCET of Dec. 23rd, 1901, p. 1799, and copies of which, printed *in extenso*, as well as of one by Dr. J. W. Washbourn, C.M.G., lantern slides illustrative of the development of carcinoma from breasts affected with chronic mastitis.

---

# NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

*Exhibition of Specimens.—Recurrent Papilloma of the Vagina.—Election of Officers.*

THE annual meeting of this society was held at Manchester on Jan. 17th, Dr. S. BUCKLEY (Manchester), the President, being in the chair.

Dr. A. DONALD (Manchester) exhibited two specimens of Tubal Mole. In each case the occurrence of hæmorrhage at about the sixth week had destroyed the life of the ovum without leading to rupture of the tube. Each tube contained a mass of clot embedding an embryo surrounded by its amnion, but with no trace of liquor amnii. No blood or clot was found in the peritoneal cavity. In one case there had been nearly two months' amenorrhœa; in the other the menstrual period had not been missed. In both the bleeding was profuse and lasted for six weeks, and a well-defined tumour was felt on one side of the uterus. The tubes were removed by abdominal section in the first case and by anterior vaginal section in the second. Both patients made a good recovery.

Dr. DONALD and Dr. W. E FOTHERGILL (Manchester) showed sections from a case of Folliculoma Ovarii Malignum The tumour, of about the size of a cocoa-nut, was hard, solid, and nodular It was removed from a single woman, aged 57 years. The clinical features of the case suggested malignancy. There were wasting, pain, and ascites. The sections showed the growth to consist of alveoli filled with epithelial cells and embedded in a fibrous stroma. The alveoli varied in size and some of them contained one or more large cells presenting the characters of egg cells in various stages of development

Dr. FOTHERGILL also showed a series of sections of Uterine Casts from cases of Membranous Dysmenorrhœa. The casts were all shown to be composed of fibrin and leucocytes. Dr. Fothergill had examined many such casts and had never ound any composed of mucosa with a lined cavity such as were frequently described.

Dr. J. B. HELLIER (Leeds) showed an Early Ruptured Tubal Gestation. The patient, a woman, aged 35 years, who had been married for 11 years, had had one doubtful abortion ome years ago. She did not suspect pregnancy and mentruation was quite regular. While cycling she was seized with sudden abdominal pain and faintness Internal hæmorrhage was suspected and abdominal section was perormed. Much dark blood-clot was found in the peritoneum. A very small tubal pregnancy had caused rupture of the right Fallopian tube, which was removed. The patient made a good recovery

Dr. W. WALTER (Manchester) showed a specimen of Fibromyoma of the Uterus removed from a single woman, aged 9 years, by Abdominal Hysterectomy. The patient had uffered from pain and hæmorrhage for some time and for ight months was unable to follow her occupation. On an. 14th abdominal section was performed. The broad igaments were tied and divided in the usual way and the terus was removed with a wedge-shaped incision just above the vaginal roof. The cervix was dilated from above downwards with a pair of Spencer Wells small forceps and a narrow gauze drain was passed through into the vagina The igatures were cut short and the peritoneum was stitched over the stump with fine silk sutures, except at a small spot in the entre where the end of the gauze served as a drain. The bdominal wall was closed with uninterrupted silkworm utures, in addition to which buried catgut was used for he muscle and fascia. The specimen, consisting of a submucous fibroid attached to the fundus and anterior wall f the uterus, was undergoing in some parts myxomatous, nd in other parts fatty, degeneration. The patient was proressing favourably so far, but without including this case Dr. Walter had just completed a series of 35 abdominal ysterectomies for myoma with one death.

Dr. WALTER also gave an account of a case of Recurrent apilloma of the Vagina. The patient, an unmarried woman, ged 37 years, was admitted into St. Mary's Hospital, Manhester, in August, 1898, complaining of bleeding from the agina between the periods which had continued off and on for several months. Her general condition was good. The uterus and other pelvic organs were healthy. Inside the vagina on the posterior wall was a small papilloma which bled readily. This was curetted and the thermo-cautery was applied freely. The microscopical character of the scrapings presented the appearance of a simple papilloma with no sign of malignancy. In November, 1898, the patient re-entered the hospital, as the papilloma was commencing to recur. The cautery was again applied. The following year on two occasions similar treatment was necessary. In 1900 the patient was re-admitted in June and in December. The patches were larger in size than formerly, but they were still quite superficial and were free from any deep-seated attachment. The cautery was applied to the affected surface Last year, in March, July, October, and December, the patches had returned and were spreading upwards on the posterior and left wall. In December it was found that infiltration into the peri-vaginal tissue on the posterior and left side had occurred since her previous visit. As the vagina was extremely narrow the perineum was divided and the part was exposed to view. A patch of mucous membrane of the size of a shilling with a raised and granulating surface, together with a small growth nearly as large as a filbert nut, were removed and the vagina was packed with gauze. The microscopical appearance of the growth showed a fibrous and elastic tissue matrix containing a considerable number of cell nests.

The following officers were elected for the year 1902:—President: Dr. S. Buckley. Honorary treasurer: Mr. Richard Favell (Sheffield). Honorary general secretary: Dr. E. Octavius Croft (Leeds) Honorary local secretaries: Dr. John Scott (Manchester), Dr. Arthur J. Wallace (Liverpool), Mr. Walter Thompson (Leeds), and Mr. Sidney F. Barber (Sheffield).

---

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF PATHOLOGY.

*Vaccinia.—Disease of Vertebræ and Humerus.*

A MEETING of this section was held on Jan. 10th, Professor E. J. MCWEENEY, the President, being in the chair.

The PRESIDENT, who was temporarily replaced in the chair by Dr. H C. EARL, read a paper on the Present State of our Knowledge as to the Etiology of Vaccinia. He said that since the work of von Thieme, Ceely, Voigt, and Fischer there could be no doubt that vaccinia was merely small-pox modified by passage through the calf. The microbic etiology of the two diseases must therefore be identical. Since the commencement of the bacteriological epoch repeated and unsuccessful endeavours had been made to establish a bacterial etiology for these maladies. Among the most recent of these attempts might be cited those of Klein, Copeman, Kent, Nakanishi, and Czaplewski and Vanselow. Mann had demonstrated that in sections of vaccine tissue appearances closely resembling micro-organisms, but really consisting of granular or rod-like precipitates of stain—mere artefacts—might be produced in the process of carrying out Gram's method. The bacillus of Nakanishi was at once recognisable by anyone familiar with the microbic flora of the calf's skin as the xerosis bacillus, which closely resembled that of diphtheria but was harmless. The micrococcus quadrigeminus of the last-named observers had been recently admitted by themselves to be devoid of all etiological relation to the vaccine process The attempts to prove that variola and vaccinia were due to a parasitic protozoon were begun in 1886 by van der Loeff, continued by L Pfeiffer of Weimar, and still further developed by Guarnieri of Pisa, and by Pfeiffer's pupil, von Wasielewsky To Guarnieri belonged the credit of having selected as the field of observation the rabbit's cornea, a transparent, non-vascular structure, in which the histological events could be observed uncomplicated by the vascular and exudative phenomena of inflammation. Guarnieri saw in the epithelial cells of the inoculated cornea rounded bodies varying in size from that of a minute coccus to about one-third of that of an epithelial nucleus They lay in the protoplasm, often close to, and even indenting, the nucleus. Amœboid movements were observable on the warm stage, and Ernst Pfeiffer saw the bodies lying *between* the epithelial cells an hour after vaccination, and *within* them a few hours later. Several observers, such as Ferroni and Massari, Salmon, and others, 12, with three deaths, were those of children; the other seven cases were adults, the oldest being 71 years of age, all of whom recovered. They were confined to one district, some of the houses being filthy, but others scrupulously clean, and in them every precaution was taken, but the infectivity of the disease was equally evident in all. He noticed pyrexia in most cases, the highest temperature being 103° F. in a child; there was abdominal pain but there were no complications; prostration and collapse were marked and were the cause of death in all the three children.

Colonel **DAVID BRUCE**, R.A.M.C., had for three months worked in a laboratory in South Africa. Amœbæ were found in one only of 30 cases examined and he doubted the existence of an amœbic dysentery. The organs were all sterile, as was the mucus, but so soon as it was mixed with fæcal matter it swarmed with bacteria, rendering the detection of the specific organism as yet impossible. He had isolated a series of the so-called "coli" group, presenting every gradation of characters, positive and negative, and agglutination experiments were conflicting. Flexner's and Shiga's bacilli belonged, he thought, to this group, no one of which was the cause. The inflammation was, he believed, always submucous in the first instance, and there might be no ulceration.

The **PRESIDENT** considered that Dr. Mott had done a public service in calling attention to a preventable disease in asylums, and the London County Council deserved credit for boldly instituting and publishing the results of the inquiry. He deprecated such aggregation even of sound men, much more of the insane and infirm, as tending to develop disease, and animadverted on the instruction of attendants in psychology while the elements of hygiene were ignored.

Dr. **MOTT**, in his reply, expressed his belief that Dr. Shaw's views had changed considerably. He, too, recognised the "weakness of the bowel" in insane paralytics, but only as tending to render them more susceptible to infection, and not as an essential cause of dysentery, which was everywhere the same disease and equally avoidable in asylums as elsewhere. At Claybury Hall 25 per cent. of the patients suffered from general paralysis, but there had been no case of dysentery in six years. Its introduction into asylums was by means of transfers, many of whom had the disease in the recurrent form, and with these the new institutions were filled. As to irrigation he knew that at Claybury Asylum patients engaged in the work ate without washing their hands and that lettuces were watered with the raw sewage.

## LIVERPOOL MEDICAL INSTITUTION.

### *Adjourned Discussion on Sir William Banks's Paper on Mammary Cancer.*

A SPECIAL *meeting of the Pathological and Microscopical* Section of the Liverpool Medical Institution was held on Jan. 23rd, Mr. **RUSHTON PARKER**, the President, being in the chair.

Mr. **KEITH W. MONSARRAT**, in opening the adjourned discussion on Sir William Banks's paper on Mammary Cancer, said that he considered it probable that carcinoma originated from a variety of causes. There was certainly evidence to show that certain of the new growths at present grouped together as carcinomata were pathologically and etiologically distinct He wished to discuss particularly the relation of carcinoma mammæ and mastitis. The study of sections did not support, in his opinion, the theory of Ribbert that carcinomatous changes were primarily due to proliferation of the connective tissue; on the contrary, the "invasion" was from the side of the epithelial element He further discussed the ways in which mastitis might conceivably be related to the carcinomatous proliferation. Although he had been successful in isolating certain organisms from cancerous growths he had not hitherto produced by their inoculation new formations that could legitimately be called carcinomatous

Dr. **A. O. RENDLE** said that whereas the cell theory threw no light on the difference between malignant and non-malignant neoplasms, the germ theory had not explained the fact that secondary growths invariably copied the primary type. Still he did not think it proper to deny the strong probability that the malignant properties of the cancer cell were due to the action of a parasite.

Mr. **H. G. PLIMMER** (London) expressed his reasons for thinking that the parasitic theory afforded a reasonable explanation of epithelial cancer. He showed lantern slides illustrating the cell inclusions on the one hand and also the organisms which he had isolated from carcinomata and the epithelial overgrowth produced by their inoculation.

Mr. **H. J. STILES** (Edinburgh) exhibited microphotographs illustrating his view that the so-called "cell inclusions" originated in degenerations and dropsical changes in the nuclei.

Dr. **R. J. M. BUCHANAN** referred to the subject in relation to heredity on the one hand and the parasitic theory on the other. In view of the transmission of minute details of conformation and disposition from parent to offspring through the agency of the spermatozoon, he thought it a legitimate consideration that peculiarities of cell reproduction should also be transmitted, and that the characteristics of cell structure as seen in cancer growths might in some way be associated with stages in karyokinesis. Dr. Buchanan exhibited a specimen of *tradescantia virginica*, showing various stages of cell division, and he drew attention to the fact that nuclei of many cells at a similar stage presented structures closely resembling cancer bodies. He referred to the importance of the centrosome in cell division and to the possibility that cancer bodies might be of centrosomic origin and expressive of an exaggerated or abnormal condition of the centrosome The question of hereditary transmission he considered applicable both to the developmental and parasitic theories: in the former as reproducing special peculiarities in the life-history of cells, in the latter as reproducing a soil susceptible in high degree to parasitic invasion. Referring to the parasitic theory in relation to the etiology of carcinoma Dr. Buchanan stated that his endeavours to grow the so-called parasite had proved unsuccessful, and that he was not fully satisfied with the results of other observers in view of the grave possibilities of contamination and the lack of evidence that inoculations of organisms isolated from cancer had reproduced this disease. This might reasonably be due to differences in experimental technique. As an advocate in the belief that cancer would ultimately be proved to be of parasitic origin he emphasised the desirability of working further afield in the direction of comparative histology and pathology in order to eliminate all source of error Apart from the purely experimental method of procedure in the endeavour to isolate an organism from, and to reproduce, cancer by inoculation of animal tissues with it, Dr. Buchanan considered that some consideration should be given to the circumstantial evidence in favour of the parasitic theory as offered by records of geographical distribution, the existence of "cancer houses," and conditions of environment associated with the occurrence of the disease Relative to this he did not accept the statement by Sir William Banks of his conviction that cancer was more prevalent in people who indulged largely in flesh meat as an article of diet. On the other hand, Dr. Buchanan was of opinion that cancer was more closely associated with indulgence in raw vegetables as articles of diet. In his belief in the parasitic theory of cancer he ventured to suggest that the parasite most probably was introduced into the body through the medium of some lower form of animal life which was in constant association with such vegetable growths as were used for food. On inquiry in certain cases of cancer he had noted that the houses in which the affected individuals resided were infested with snails to a remarkable degree, and in many cases the victims had been addicted to indulgence in salads as articles of diet.

Mr. **GEORGE G HAMILTON**, who showed a number of casts, drawings, and microscopical sections, regarded chronic mastitis as a very serious disease and was in the habit of incising breasts so affected at an early stage under a local anæsthetic and removing portions for examination. He had seen tuberculosis of the breast mistaken for carcinoma in two instances. He did not agree with some of Mr. Plimmer's views on the physiological properties of epithelium, and particularly the idea that it exercised universally a protective property against invasion; he looked upon experiments on animals by feeding with tuberculous material as evidence against such a conception

The **PRESIDENT** drew attention to the claims of M. Doyen to have discovered a micrococcus which he maintains to be the universal cause of new growths.

Sir **WILLIAM BANKS**, in his reply, referred to Mr. Plimmer's statement that the cell inclusions of carcinoma were peculiar to that disease and were not found in normal tissues or in other morbid conditions. He showed a series of blow.—Mr. J. W. Gooch introduced a discussion upon the question, "What is the Best Mode of Conducting Normal Labour?" After a few brief introductory remarks the questions of the choice and arrangement of the lying-in room and the dress and preparation of the patient were entered into as far as possible. The methods adopted for cleansing the hands and the question of the lubricant were discussed in detail, and a description was given of the means often adopted by the speaker for the purpose of expediting the normal course of labour. Mr. Gooch advocated a more frequent use of the forceps than is commonly advised in the schools, the short instrument of Assilini being much commended. The uses of ergot and chloroform in the various stages of labour were next discussed and allusion was made to the advantages to be gained by the application of the binder before delivery. The question of the douche after labour was next entered into, the opinion of the speaker being that bathing the external genitals with antiseptics was of more importance than the douche.—The discussion was continued by Mr. J. Brickwell (Slough), Dr. G. J. Sealy (Weybridge), Mr. W. A U. Thomson (Maidenhead), and Mr. W. Netterville Barron (Ascot), all of whom were in agreement with Mr. Gooch in the matter of frequent use of forceps, while on the questions of the use of chloroform and ergot and of the douche considerable diversity of opinion was found to prevail.—Dr. P. J. A. Seccombe of West Drayton was elected by ballot a member of the society.

**Newcastle-upon-Tyne Clinical Society.**—A meeting of this society was held on Jan. 16th, Dr. O. W. Ogden, the President, being in the chair.—Dr R. P. Ranken Lyle showed a case with Sequestration Axillary Mammæ. In each axilla there was a mass of the size of a kidney. The mass in the left axilla was rather larger than was that in the right. The masses had a soft, solid, lobulated feel. The mass in the left axilla being a little inflamed was rather tender. There were no supernumerary nipples. The patient was suckling her third child. The history of these masses was that after her second parturition she noticed a small lump of about the size of a walnut in each axilla On the third day after her last—i.e., her third—parturition these lumps became much bigger. Dr. Lyle pointed out that there were some lobules separated from the breast near the sternum. He considered sequestration mammæ to be commonest near the sternum or in the groin, while in the axilla they were rare He recommended these masses to be excised, as he considered that they would become larger and more inflamed if another pregnancy occurred.—Mr W. G. Richardson showed a specimen of Molluscum Fibrosum. The growth, which was of the size of a child's head, had been removed from the region of the right elbow of a man, aged 50 years. The growth was covered with thickened, dark-brown, puckered skin. The man had had this thick skin all his life and had suffered from the growth for 11 months Sections of the thick skin showed it to contain a large amount of fibrous tissue, while sections of the growth underlying it showed it to be spindle-celled sarcoma. The patient recovered from the operation and went back to the country where he was a farmer. The further history of the case was that in four months he developed some lung trouble with hæmoptysis and died. Mr. Richardson considered that he had died from secondary growths in the lung. He considered that the new growth in the skin was molluscum fibrosum. He referred to Dr. Alexis Thomson's book, where cases of molluscum fibrosum had been shown to be of the nature of false neuromata, the thickened skin being due to overgrowth of the endoneurium of the cutaneous nerves.

**Harveian Society of London.**—The annual meeting of this society was held on Jan. 16th, Dr. D. B. Lees, the President, being in the chair.—The following gentlemen were unanimously elected officers of the society for the year 1902:—President: Mr. W. Watson Cheyne. Vice-Presidents: Dr. H. A. Caley, Dr. F. W. Cock, Mr. J. Jackson Clarke, and Dr. L. G. Guthrie. Treasurer: Mr. Edmund W. Roughton. Honorary secretaries: Dr. Edmund Cautley and Mr. Francis Jaffrey. Council: Dr. Edgar G. Bulleid, Dr. C. Buttar, Mr. H. S. Collier, Dr. A. Eddowes, Mr. Raymond Johnson, Dr. D. B. Lees, Dr. H. J. Macevoy, Mr. Hubert C. Phillips, Dr. J. S. Risien Russell, Mr. J. Sefton Sewill, Dr. G. A. Sutherland, and Dr. James Taylor.—The reports of the council and the treasurer showed that the number of members exceeded 400 and that the society had a credit balance of over £125.—Votes of thanks to the President, the treasurer (Mr. Edmund Roughton), and the secretaries, especially the retiring secretary (Mr. Hubert C. Phillips), for their valuable services during the year were carried and were suitably acknowledged.—The President delivered an address on the Heart of the Child, which appears in full at p. 279 of the present issue of The Lancet. A vote of thanks to the President for his interesting address was carried with acclamation.—On receiving the report of the election from the scrutineers (Dr. E. Symes-Thompson and Dr. W. H. Blenkinsop) the President declared the result and inducted the new President (Mr. W. Watson Cheyne) into the chair. Mr. Watson Cheyne briefly returned thanks for the honour conferred on him and declared the conversazione open.—A lantern demonstration was given by Mr. Frank Crosbie, showing a method of producing photographic transparencies in colour — Mr. Noble Smith exhibited microscopical illustrations of Abnormal Gaits, &c., in Various Nervous Diseases, and a collection of Histological and other Water-colour Drawings. —Mr. Hubert C. Phillips, F.E S., exhibited a valuable collection of British Lepidoptera with Original Water-colour Drawings from Nature.—Music was provided by the string band of His Majesty's Royal Horse Guards (Blue), by permission of Colonel Lord Binning.

**Æsculapian Society of London.**—A meeting of this society was held on Jan. 24th, Dr. Arthur T. Davies the President, being in the chair.—Mr. A. Q. Silcock read the notes of two cases The first case was that of a man, aged 30 years, who was admitted to St. Mary's Hospital with a history of Abdominal Pain of one week's duration. On admission the patient had a distressed look, with thoracic respirations and general tenderness over the abdomen which was specially marked in the right iliac fossa. There was no distension. The temperature was 100° F. Appendicitis was diagnosed. At the time of operation, when under the anæsthetic, a rounded, hard, non-fluctuating tumour was found reaching from the lower edge of the liver to the umbilicus. This was opened. It proved to be the gall-bladder, and a large quantity (a pint) of mucus was evacuated, followed by some muco-purulent discharge. No gall-stones were found. The gall-bladder was sutured to the abdominal wound and a biliary fistula resulted. Otherwise the patient made an uninterrupted recovery. In the second case the patient, a man, was admitted into St. Mary's Hospital under medical treatment with a history of Marked Jaundice of three months' duration The liver was enlarged and the gall-bladder was distended. No surgical treatment was adopted and the patient finally developed purpura, became comatose, and died. Post-mortem the gall-bladder and the hepatic and common bile ducts were very much distended with mucus The head of the pancreas was hard and swollen, but whether from chronic inflammation or from new growth had not yet been determined. There was some perihepatitis and scarring of the edge of the liver, probably syphilitic.—In connexion with the first of the cases Mr. A. W. Galloway related cases bearing on the difficulty in making an accurate diagnosis in appendicitis.—The point raised by Mr. Silcock for discussion with regard to the second case was whether it would not have been advisable to call in surgical aid in the treatment of the case with the view of opening and draining the gall-bladder and thus relieving the symptoms.—The President concurred in this view.—Mr. R. Brown also agreed with Mr. Silcock and he drew attention to the similarity of the fatal symptoms in this case to those of acute yellow atrophy of the liver.

**Glasgow Southern Medical Society.**—An ordinary meeting of this society was held on Jan. 23rd, Dr. John Stewart, the President, being in the chair.—Mr. R. H. Parry showed the following group of surgical cases—viz., (1) a case in which there had been Rupture of the Thoracic Duct; (2) Excision of a Stricture of the Urethra and Immediate Approximation of the Divided Ends of the Urethra; (3) Excision of the Tongue and Half of the Lower Jaw for Carcinoma of the Floor of the Mouth; (4) Excision of Tuberculous Glands from the Anterior and Posterior Triangles of the Neck through an Incision in the Hairy Scalp; (5) a Cerebral Tumour (Glioma Sarcoma) removed by raising a large osteoplastic flap; (6) Injury to the Fifth Cervical Nerve, Paralysis of the Deltoid, Biceps, Brachialis Anticus, and Supinator Longus Muscles; (7) Idiopathic Dilatation of the Colon in the treatment of which the ileum had been joined to the rectum; (8) Rupture of the Gall-bladder, Escape of Pus into the had endeavoured to explain these bodies as resulting from irritation of a non specific kind But Hückel, whilst not admitting their parasitic nature, had been led to infer that they were the result of some alteration of the cell produced by the parasite or its toxin E Pfeiffer had shown that lymph that had lost its activity through filtration or otherwise was incapable of producing "bodies in the corneal epithelium Wasielewski had propagated the vaccine virus on the rabbits' cornea for 43 generations, and used the corneal epithelium scraped off the forty third consecutive rabbit for vaccinating children and produced a large percentage of typical vesicles The only feature presented by such virulent epithelium and not presented under any circumstances by normal or otherwise irritated epithelium was the presence of the bodies described by Guarnieri For this reason it was difficult to escape from the conclusion that the "bodies ' were the carriers of the infection Beyond the seeming existence of a nucleus the most careful examination had failed to reveal much structure in the "bodies" as found in the infected epithelium, and as to their reproduction and developmental cycle little or nothing was known Through the kindness of Dr Gustave Mann of the Physiological Laboratory, Oxford, the President was enabled to show the several stages in the evolution of the vaccine vesicle, illustrated by lantern slides and actual preparations and he also exhibited slides and sections of the inoculated rabbit cornea in which every cell was seen to harbour one or more "bodies "

Mr J P DOYLE read a paper on Disease of Two Upper Cervical Vertebræ and Upper Part of the Left Humerus The patient, a boy, aged nine years was admitted to St Joseph s Hospital under the care of Mr Doyle, on Sept 6th 1901 On Dec 4th he died suddenly At the necropsy Mr Doyle found that the anterior surface of the occipital bone and the first and second cervical vertebræ with their intermediate anterior portion were very much eroded The odontoid process of the axis was considerably diseased and by the giving way of the transverse ligament the process pressed on the upper portion of the spinal cord and thus caused sudden death —Dr MONTGOMERY moved Dr WATSON seconded and it was resolved that Mr Doyle s paper should be sent to the Reference Committee

---

SHEFFIELD MEDICO CHIRURGICAL SOCIETY —A meeting of this society was held on Jan 16th Dr O H Willey, the President, being in the chair —Dr S White exhibited the following specimens and case 1 Phosphatic Calculi and Prostatic Tissue removed Suprapubically from a patient, aged 63 years who had been suffering from enlarged prostate 2. An Excised Gastric Ulcer removed from the Anterior Wall of the Stomach of a man, aged 24 years The ulcer had existed for two years and had perforated 18 months previously, but owing to extensive adhesions the general peritoneum had not been fouled The ulcer was about an inch in diameter and was funnel shaped The walls of the stomach around the ulcer were fully one third of an inch in thickness and a dense band of fibrous tissue united the ulcerated area to the anterior abdominal wall The patient was now quite free from his old symptoms 3 A child, aged two years the subject of Retroversion of the Bladder, in whom the ureters had been transplanted into the rectum by the extra peritoneal method described by Dr Peters of Canada This operation was described and criticised —Dr A. J Hall showed the following cases —1 A case of Acute Myelitis in which the first lesion had occurred in the lower thoracic region of the cord The onset was accompanied by pyrexia diarrhœa, and vomiting An interesting feature was the presence of a circular ring of acute bedsore due to the pressure of the rim of a chamber pot on which the patient had been placed for some hours before admission on account of his diarrhœa. About five days after his first attack paralysis of both arms dysphagia and paralysis of the tongue occurred, and the patient became temporarily insane These symptoms lasted for about a week. The patient made a complete recovery 2. A case of Occupation Neurosis The patient was a single man aged 43 years, a bricklayer, who had noticed weakness of the right hand following upon influenza two years before. The loss of power was most marked on using his trowel, and was accompanied by numbness and occasional stiffness Tremors and pain occurred on excitement To show the psychical element in the condition the facts were adduced that the patient witnessed the sudden death of his father by accident five years ago and that the affection was improved by stimulants and arrested by a rubber ring on the finger 3 A case of Trade Eczema of 11 years' duration affecting the hands and arms in a polisher who worked in rouge The patient had been previously shown to the society and since then had been applying calamine gelatin daily over the dorsa of the fingers, hands, and forearms, with the result that she had been perfectly free from eczema for several weeks —Dr G Wilkinson related two cases of Successful Operation for Ruptured Intestine In the first case a boy, aged 12 years, was stabbed in the lower abdomen with a pocket knife. The intestine was wounded in two places and the mesentery in one There were much bleeding and some extravasation of fæces Resection of the wounded portion of intestine was performed and the ends were united over a Mayo Robson bone bobbin The second case was that of a boy, aged 11 years, who was kicked in the abdomen by a horse Dr Wilkinson saw him 24 hours later when signs of acute general peritonitis were present The abdomen was opened by an incision eight inches in length in the middle line A circular hole half an inch in diameter was found in the ileum and was sutured A large fæcal collection was found in the lower part of the abdomen and general septic peritonitis was present After wiping out the extravasated fæcal matter thorough irrigation of the abdomen was performed The abdomen was closed without drainage Though much collapsed after the operation the patient eventually made a good recovery

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY —A meeting of this society was held on Jan 15th Dr E O Kingdon, the President, being in the chair —Miss Sarah Gray read a paper entitled, "Is Alcohol properly described as a Stimulant? The paper dealt with the question whether the action of alcohol on the human body was predominantly that of a stimulant (defined as "something which produces activity ) or whether by inhibiting nervous centres in inverse order of their development it produced only a factitious and transitory display of energy due to over-action of centres below those inhibited The effect on nervous tissue, especially on that of the highest cerebral centres was regarded as of primary importance Experimental work by Krapelin, Furer, Aschaffenberg, Hodge Killogg, and others was cited to show that this effect was uniformly depressant for higher centres and also depressant after a brief initial acceleration for lower centres With regard to muscular work the experiments of Frey and Destree were quoted as supporting those of Parkes The effect on the heart was particularly discussed and in the absence of decisive physiological and pathological experiment clinical evidence with regard to treatment of diseases, such as enteric fever, diphtheria, and septic peritonitis, with and without alcohol, was adduced from Knox Bond, MacNicholl of New York G B Davis of Chicago, and others Their evidence seemed to show that the results obtained without alcohol were better than were those which were obtained with alcohol, when "true' cardiac stimulants were used, such as caffeine and strychnine Mortality, it was stated, in septic peritonitis had been reduced by such treatment from 85 5 per cent to 14 per cent. The results of treatment at the London Temperance Hospital were also cited The effect of alcohol on digestion was very briefly discussed In conclusion, a plea for more exact study of the subject and the formation of more accurate and fully-considered views of the action of alcohol as a drug was urged —In the discussion which followed the following members took part—viz., the President Dr C H Cattle, Dr A Fulton Dr J S Bolton Dr W Hunter, Mr T Gerity, Mr J. H Cox, and Dr T A Clinch and Miss Gray replied

WINDSOR AND DISTRICT MEDICAL SOCIETY —The fourth meeting of the session of this society was held on Jan 22nd Mr W B Holderness J P, the President, being in the chair —Microscopical preparations were exhibited illustrating certain morbid conditions of the Ovary, including Papilloma Carcinoma and Cystic Disease. The sections were lent by Dr G Leslie Eastes —The President showed 1 A case of Locomotor Ataxia in a man, aged 46 years There was very marked affection of the knee joints and the Argyll Robertson phenomenon was present There was a distinct specific history 2. A case of Morbus Cordis following an attack of Subacute Rheumatism Both apical and basic murmurs were present.—Captain F. S Brereton R.A.M.C., showed a case of Enlargement of the Testis following a and arrangement of its material and in the compilation of the work.

---

*A Short Practice of Midwifery, embodying the Treatment adopted in the Rotunda Hospital, Dublin* By HENRY JELLETT, B A., M.D. Dub., F.R C.P. Irel. Third edition, revised and enlarged, with 124 Illustrations and an Appendix containing the Statistics of the Hospital for the last 11 years London: J. & A. Churchill. 1901. Crown 8vo. Pp. 533. Price 8*s.* 6*d.*

IN this, the third edition of this manual, Dr. Jellett has given up the unsatisfactory task of attempting to write a handbook suitable both for nurses and for students and medical practitioners. He has accordingly included a considerable amount of new material in the present edition, while he has prepared a second and shortened one for the use of nurses. New chapters have been written upon Pregnancy and its Phenomena, the Ovum, and Obstructed Delivery; while the chapters upon Obstetrical Diagnosis, on the Different Presentations, on Obstetrical Operations, on Infant Feeding, and on Infantile Diseases have been made fuller and more complete. We notice that on p. 16 Dr. Jellett gives the old familiar but utterly erroneous table of the height of the fundus uteri at the various months of pregnancy. How absurd the statement is that the fundus of the uterus is at the level of the top of the symphysis pubis at the end of the fourth month of pregnancy is shown by the fact that the fundus of the non-pregnant uterus in the anatomical position of the body, in which all such measurements must be taken, is one and a quarter inches above the upper border of the symphysis pubis. In other words, the uterus at the end of the fourth month of pregnancy is actually lower in the abdomen, if we are to believe this table, than the non-pregnant uterus. The very diagram (Fig. 6) introduced to illustrate the table shows that this is not so, while a reference to either Bayer's or Waldeyer's frozen sections of the pregnant uterus at the third and fourth months of pregnancy respectively would have shown to Dr. Jellett the worthlessness of this table. In Bayer's specimen the fundus of the uterus is at a level of 70 millimetres ($2\frac{4}{5}$ inches) above the symphysis, the total length of the body of the uterus being 85 millimetres ($3\frac{3}{8}$ inches), while in Waldeyer's case the fundus uteri is 125 millimetres (five inches) above the symphysis or at a height equal to the total length of the body of the uterus in this particular specimen—that is to say, the whole of the body of the uterus is in the abdominal cavity, a fact which Pinard demonstrated years ago by clinical observations to be the case as early as the end of the third month of pregnancy and which he has frequently insisted upon since. In other respects the book has been well revised and brought up to date. The new illustrations are good and useful and we can recommend this third edition to students and medical practitioners as cordially as we have done the former ones.

---

*Bath Waters: A Rational Account of their Nature and Use.* By PRESTON KING, M D. Cantab., Honorary Physician to the Royal Mineral Water Hospital, Bath; Honorary Assistant Physician to the Royal United Hospital, Bath. With an Historical Sketch by S. BARING GOULD, M.A. Bristol: J. W. Arrowsmith. Pp. 128.

THE object of the author of this volume is to give a short and rational account of the Bath thermal waters and also of the principal diseases which may be most successfully treated by suitable applications of these waters. Dr. King has succeeded well in his endeavours to render the volume a purely medical one. It is not easy to avoid making such a book a "medical guide"—a class of literature to which we have strong objections. Dr. King, however, steers perfectly clear of such temptations. The account of the "source and heat of the waters" is an interesting one. He quotes the researches of Mr. J. W. Morris of Bath who came to the conclusion that the mineral waters have their origin in some volcanic region to which marine sources have made contribution. The description of the bath-rooms and appliances is well carried out and the illustrations are excellent. The chapters on the Treatment of Rheumatism, Gout, and Rheumatoid Arthritis will well repay perusal and the beautifully executed illustrations add to the value of the letterpress. Dr. King draws attention to certain symptoms in rheumatoid arthritis which are apt to escape notice, such as the "fibrillar twitchings," persistent and troublesome cramps, the latter occurring chiefly at night and sometimes causing great distress. The pigmentation which so frequently manifests itself is also described and a capital reproduction of a photograph of the "butterfly" pigmentation is given. The therapeutic value of the Bath waters is fully recognised and the volume now before us forms a useful epitome of their mode of use and methods of application.

---

*The Protozoa.* By GARY N. CALKINS, Ph.D. Being Vol. VI. of the Columbia University Biological Series. New York: The Macmillan Co. 1901. Pp. xvi. + 347, with 153 figures in the text. 8vo. Price 12*s.* 6*d.* net.

THIS tall and slim volume is a natural sequel to a previous volume in the series dealing with the cell. The main objection to it is its slender size, for the quality of the book is more to be praised than the quantity. The group of the protozoa with which it deals is enormous in numbers and omnipresent. No drop of water, save that which is distilled, no speck of mud, no damp leaf, and no animal body are without some of these tiny creatures. To condense the immense mass of information that we possess respecting the "urthiere," as the Germans term these truly primitive animals, into so few pages does not appear to us to be quite adequate treatment. One result is that the author, conscientious in giving tables of classification of all the families and larger groups after the chapters dealing with each, is forced to retail name after name of protozoa which he has not even mentioned in the most casual way in the preceding letterpress. It may be freely conceded, however, that such matters as the author does lay before us are skilfully handled and amply illustrated. The reader will unquestionably derive the main outlines of a knowledge of the protozoa from a perusal of this work. It is also a work that is distinctly to be read. It is not sufficiently encyclopædic to form a work of reference; it will, however, be read with approbation. The style is easy and this ease is not acquired at the expense of depth and detail. Abundant illustrations further elucidate the text; all of these are clear and many are of really excellent execution. Some are from actual preparations made by the author, and the inclusion of such figures is legitimate on the part of a naturalist who has made a special study of the group and, moreover, tends to confirm the confidence which the reader will feel in his instructor. The bibliography is fairly full, but by no means exhaustive We find omitted, for example, Professor Geddes's researches on the "yellow cells" of radiolarians, and Professor Minchin's observations upon gregarines The author might also perhaps have said something about a curious form of gregarine, referred by M. Labbé to the genus monocystis, which Mr. Beddard described from the body cavity of an exotic earthworm some years since. However, as already implied, it is not possible to pack into 310 pages even the briefest mention of a host of interesting forms.

The entire correspondence between a single protozoon and a single cell of one of the higher animals is duly insisted upon by the author, a correspondence which is a comparatively new generalisation in zoology, but, curiously enough, was suggested in a dim way as long ago as in the days of

Peritoneal Cavity, followed by Diffuse Purulent Peritonitis; (9) Idiopathic Dilatation of the Stomach and Removal of a Large Stricture of the Lower End of the Ileum; and (10) cases illustrating the Common Errors in the Diagnosis of Lesions on the Right Side of the Abdomen.—At the close of the demonstration Mr. Parry received the cordial thanks of the society on the motion of the President.

**Dermatological Society of Great Britain and Ireland.**—A meeting of this society was held on Jan. 22nd, Dr. A. J. Harrison, the President, being in the chair.—Dr. A. Eddowes showed a case of Lichen Planus.—Dr. N. Meachen showed a case of Tuberculides.—Dr. P. S. Abraham showed: (1) A case of Parakeratosis Variegata in a young woman; (2) Lupus Erythematosus; (3) Lupus Vulgaris on the Elbow; and (4) Erythema ab Igne in a boy, aged 10 years.—Dr. Graham Little showed: (1) A case of Cutaneous Tuberculides; (2) Doubtful Eruption in an infant, possibly specific, but considered by some members to be a bromide eruption; (3) Comedones on the back and front of the chest in a young child, aged 12 months; and (4) a case of Œdema Neonatorum.—Mr. A. Shillitoe showed: (1) A case of Small Papular (Lichenoid) Syphilide; (2) Leukoplasia Cervicis; (3) Tertiary Tuberculated Syphilide; and (4) Secondary Eruption in a Much-tattooed Subject.—Dr. Little also showed microscopical specimens from a case of Syphilis with Keloid-like Eruption, exhibited by Mr. Shillitoe at a former meeting.—Dr. Eddowes also showed microscopical specimens: (1) Papule of Eczema; (2) Micro-bacilli on a Hair taken from a Leucodermic Patch; and (3) Epithelioma of the Face.

# Reviews and Notices of Books.

*The Surgical and Medical History of the Naval War between Japan and China during 1894-95.* Translated from the original Japanese Report, under the direction of Baron SANEYOSHI, F.R.C.S. Eng., &c., Director-General of the Medical Department of the Imperial Japanese Navy, by S. SUZUKI, M.R.C.S. Eng., L.R.C.P. Lond., &c., Deputy-Inspector-General of Hospitals and Fleets, Imperial Japanese Navy. Tokio: Printed by the Tokio Printing Company, Limited. 1901. Pp. 544.

THE Japanese are a very remarkable people. They have given so many proofs of their national courage, patriotism, enterprise, and energy—physical and intellectual—in their comparatively brief historical record that no one doubts their possession of these qualities or hesitates to form a high opinion as to the part which Japan is destined to play in the history of the future. It is not merely that the receptive faculties of the Japanese are so large and keen—for they share these with many Eastern peoples—but it is because they are so progressive and teachable that they assimilate and develop what they learn and turn it to account that they naturally excite a good deal of speculative interest as to their future.

The publication of this work, which is likely to prove valuable and to be frequently referred to hereafter, may be taken, for example, as a case in point. Japan proved herself to be no mean naval power in her war with China, and animated by a desire to put the medical history of that war on record her naval medical service has had the enterprise and industry to give effect to it by the preparation and production of the large and well-illustrated report before us. Its interest mainly consists in the fact that while so much has been written, and is still being written, about wounds received in wars on land we possess no medical history of naval warfare at sea. As is pertinently pointed out in the preface, the lessons of Trafalgar and of Lissa and of the war between Chile and Peru have been lost to us, and there has been no previous experience of the treatment of wounded on ships since the modern revolution in naval warfare. It is needless to say that a naval battle is a very much more formidable affair than a land fight. Apart from the fact that a ship may be suddenly sunk or destroyed, the damage effected by the explosion of shells is often wholesale and attended with fearful consequences to the ship and the gravest loss of life and injuries to those on board. In some of the naval engagements of this war the wounded could not be treated surgically because no surgeons were left alive to attend to them. We have only to turn to the illustrations in this volume showing the state of the *Matsushima* and *Hiyei* caused by the explosion of shells to see how this occurred. The subject is one which has a direct bearing upon the care and management of the wounded on shipboard, which is discussed by the authors. In the men-of-war of Nelson's time there was a wide hatch in the centre of the ship, extending virtually from the upper deck to the bottom and below the water-line, and this was well adapted for use as a spacious surgery. But nowadays, when the great object is to make naval vessels the most powerful, swiftest, and best possible engines of destruction of their kind afloat, the provision for the treatment and accommodation of the sick and wounded in the best and most suitable position is an infinitely more difficult matter. Ships are propelled by steam power and constructed in watertight compartments, and engine rooms, coal-bunks, and numerous other essential provisions have to be taken into account. The sick-bay or surgery of a ship of war should be conveniently placed for collecting the wounded and for securing, as far as practicable, their safety from shell-fire—desiderata which, however obvious, must frequently be unattainable. All the arrangements for the collection and removal of the wounded and for supplying them with surgical aid on shipboard during, or directly after, a naval action require to be carefully and systematically thought out, and should be held in remembrance in drawing up and designing plans of war-vessels. It would be interesting to learn what has been attempted or done in these respects in our own navy. In future naval wars some system will have to be organised for relieving ships of their wounded after an engagement by a fleet of vessels specially designed for the purpose—to act as bearer columns now do on land in stripping a battle-field of its wounded.

The book has been translated into excellent English. Reference is made in it to, and a brief description is given of, the naval battles of Phung-do and Yalû, the attacks of the Japanese upon Tan-chow, Wei-hai-wei, the Pescadores, and those upon Keelung, Takau, and Anping; also to the bombardments of Hwa-yuan-kow, Talien Bay, Port Arthur, and Yingching Bay. This is introductory, however, to the special subject to which the report is devoted—namely, the condition of the killed and wounded in the various actions and the diseases and injuries in the Japan-China war during 1894-95. In the description of the battle of Yalû the facts concerning the *Matsushima* and some other vessels are worth reading. A brief history of the killed and wounded is followed by the statistics of injuries and the causes and classification of wounds and their complications, this section ending with a chapter on the management of the wounded. This part of the volume also includes numerous surgical and clinical details and much curious and instructive information, together with a history of several remarkable cases of injury, and are illustrated by numerous large and coloured plates. Other sections deal with diseases and injuries (exclusive of the killed and wounded in the actions during the war), sanitary conditions, and the work done in the naval hospitals. The book is a little mine of information in regard to the surgical and medical history of the naval war between Japan and China and a variety of subjects connected therewith, and it is scarcely necessary to add that much time and labour must have been bestowed on the collection may precede the earliest inspiratory crepitations of pneumonia. The treatment of the disease is generally well described, but the majority of physicians will scarcely agree with Sir J. Moore's statement, "Many—probably most—pneumonic patients are better without stimulants." We are certainly of opinion that in the majority of cases of pneumonia stimulants are required and that alcohol is one of the most valuable drugs that can be employed in the treatment of this affection.

*Blackpool as a Health Resort.* By THOMAS CARR, M.D. Durh. Manchester: Abel Heywood and Son. 1901. Pp. 78. 1*s*.—The history of Blackpool is uninteresting. Much of the information given by Dr. Carr is taken from such obvious sources as the annual reports of the medical officer of health, while an elementary essay on climatology is padding, although the author suggests that the general principles of climatology are discussed so that we may understand the climate of Blackpool in particular. The vital statistics of Blackpool are dealt with in a few lines, Dr. Carr stating that "the practical conclusion that those of us who have studied these conditions (i e., age, sex, and occupation of the residents) have come to is that scores of people who would either be chronic invalids or have died under less favourable surroundings are living yet at Blackpool." What sort of value is Dr. Carr's pronouncement, backed by unnamed authorities and supported by no figures? In a chapter headed "Cases Specially Benefitted (*sic*) by Residence at Blackpool" it is claimed that residence in the Lancashire town will improve sufferers from (1) nervous diseases; (2) chest complaints; (3) troubles associated with the digestive organs; and (4) constitutional maladies. This is a large order. The last chapter contains notes on the Hôtel Métropole and other hydropathic and boarding-establishments, the names of the proprietors or managers being in several instances mentioned in an obliging manner. We are not favourably impressed with this *brochure*, for we cannot conceive that it will be of any use to anyone except to Dr. Carr, who places under his name on the title page 13 lines describing his past and present professional positions.

## JOURNALS AND MAGAZINES.

*The Journal of Anatomy and Physiology.* Conducted by Sir WILLIAM TURNER, K C.B., F.R.S.; D. J. CUNNINGHAM, M.D., F.R S.; G. S. HUNTINGTON, M.D.; A. MACALISTER, M.D., F.R.S.; and J. G. M'KENDRICK, M.D., F.R.S. Vol. XXXVI. New series. Vol. XVI., Part 2. January, 1902 With Plates and Figures in the Text. London: Charles Griffin and Co., Limited. Pp. 50. Price 6*s* —The articles contained in this part are the following: 1. The Relation of Structure and Function as Illustrated by the Form of the Lowest Epiphyseal Suture of the Femur, by Arthur Thomson, M.B. Edin, Professor of Human Anatomy, Oxford University. The conclusion arrived at by Professor Thomson from an examination of the specimens at his disposal is, that structure in this instance is determined by function. 2. The Form and Form Relations of the Human Cerebral Ventricular Cavity, by J. O. Wakelin Barratt, M.D Lond. The determination of the form of the ventricular cavities of the brain is shown in this paper to be more difficult than might at first sight appear and to require much attention to details. Many illustrations are given and the result of the method pursued seems to be very satisfactory. 3. The Peritoneum of the Pelvic Cavity, by A. Francis Dixon, M.B. Dub., Professor of Anatomy, University College, Cardiff, and Ambrose Birmingham, M.D. R.U.I., Professor of Anatomy, Catholic University, Dublin, with three plates. The description is clear and the plates are well executed. 4. Salmo Salar, the Digestive Tract in Kelts, by J. Kingston Barton, M.R.C.P. Lond., with two plates. This paper contains an account of the contents of the alimentary canal in a healthy kelt taken from the Hampshire Avon and of the histological characters of the intestinal walls. Many fat droplets were found in the lacteal system. 5. Some Observations on the Origin and Nature of the So-called Hydatids of Morgagni found in Men and Women, with especial reference to the fate of the Müllerian Duct in the Epididymis, by John H. Watson, M R.C.S. Eng., assistant demonstrator of anatomy, London Hospital. This is an excellent article in which the nature of the "sessile" hydatid and of the "pedunculated" hydatid is well worked out, the former being shown to be of Müllerian origin and the latter the true hydatid of Morgagni which usually springs from the anterior layer of the salpinx, occasionally from the fimbriated extremity of the Fallopian tube, and which can invariably be traced to the parovarium through the broad ligament. This pedunculated cyst is the homologue of the stalked hydatid attached to the epididymis of the male, both being derivatives of either the mesonephros or the anterior end of the Wolffian duct. The cyst occurring at the base of the fimbria ovarica is of doubtful origin, and is possibly a distended mucous gland or a cyst of the tubo-parovarian duct. 6. Hyoid Apparatus in Man in which a separate Epi-hyal Bone was Developed, by Professor Sir William Turner. 7. The last article is by Walter H. Gaskell, M.D. Cantab., LL D., F.R.S., on the Origin of Vertebrates, deduced from the Study of Ammocœtes, dealing particularly with the origin of the eighth cranial nerve.

# New Inventions.

## BILLROTH'S WATERPROOF CAMBRIC.

WE have received from Messrs. L. Paechtner and Co., of 40, Queen-street, Cheapside, a sample piece of a new waterproof material, called Billroth's waterproof cambric. It is said to be extensively used on the continent for purposes where a material is required which is impervious to water. Thus it can be employed to cover fomentations, or in place of mackintosh sheets for use in operations, and for aprons for surgeons and nurses. We have examined the sample sent to us; it is a yellowish material, apparently prepared by some method similar to that by which "oil-silk" is made We find that it is quite impervious to water, even after prolonged boiling; we may therefore conclude that the makers' claim that this material may be sterilised is well founded. This is a great advantage as ordinary mackintosh sheets cannot obviously stand sterilisation by heat. It is thin and somewhat translucent in appearance, but it seems to be strong. We consider that it is likely to prove of service in many uses for which rubber-covered materials are now employed. We understand that the wholesale price is approximately at the rate of 1*s*. a square yard; it is therefore considerably cheaper than mackintosh sheeting.

## IMPROVED VACCINATION SHIELD.

EXPERIENCE has shown the general practitioner that while some sort of protection should be afforded to vaccination vesicles the less they are interfered with by anything coming in actual contact with them the better, unless, perhaps, a discharging stage should require attention. And for all practical purposes the less cumbersome a vesicle-guard is the better. I have devised one which has been made for me by Messrs. Arnold and Sons of West Smithfield, London, E C., that seems to me to be as effectual as it is simple. It is made of aluminium and is fixed to the skin by means of oblong pieces of sticking plaster placed over the broadened end of it. Being fixed parallel to the long axis of the arm it meets with hardly any pressure or friction from clothing when applied. One or two turns of a bandage may complete adjustment if desirable. One of the greatest advantages of this form of guard is that the vesicles can always be seen, and treated when discharging, without removing the guard If it is placed in position after the operation has been performed the wound is kept from being irritated, and if the first

Oken. That naturalist held that the appearance of "infusorians" in water containing decaying animal or vegetable matter was due to the resolution of the animal bodies into their primordial "vesicles," and the same view was held by others at or about the same time. Of late years many and remarkable proofs of the justice of considering these minute creatures as each equivalent to a single cell have been added. Not the least remarkable of these is the occasional extrusion by protozoa of fragments apparently quite comparable with the "polar bodies" invariably extruded by the egg during its maturation. Even that mysterious and little-understood body, the "centrosome," has at length turned up in the protozoa. The earlier observers were baffled by the extreme complexity of the protozoan body as compared with any other animal or vegetable cell. A historical introduction deals with such matters, and the main problems, physiological as well as anatomical, of the group are dealt with after the systematic account of the varied forms which constitute this most ubiquitous order of creatures.

---

*The Surgical Anatomy and Operative Surgery of the Middle Ear.* By A. BROCA, Surgeon to the Trousseau Hospital, Paris, and Supernumerary Professor to the Faculty of Medicine of Paris. Translated by P. MACLEOD YEARSLEY, F.R.C.S. Eng., Surgeon to the Royal Ear Hospital. London: Rebman, Limited. 1901. Pp. 62. Price *3s. 6d.*

PROFESSOR BROCA has divided his monograph into three parts—the Surgical Anatomy, the Operative Procedures, and an Atlas. *The anatomical part is very thorough. It is pointed* out that the supra-meatal spine is not developed from the tympanic ring, a fact which is often overlooked, but proceeds from a point known as the "epitympanal." The author passes severe strictures on those surgeons who divide the facial nerve and who expose the lateral sinus. We quite agree with him in thinking that division of the facial nerve is usually inexcusable and even culpable, but as to exposing the sinus that is entirely a matter of opinion, and Mr. Yearsley has added a footnote without due regard to the context. Professor Broca describes in detail (1) opening the antrum alone, or the so-called Schwartze operation; and (2) opening the antrum and tympanum. In the latter case incision of the external meatus at its upper and posterior part is advised, and Professor Broca still advocates non-closure of the post-auricular wound—a procedure which has gradually fallen into disrepute in England; we cannot help believing that the immediate suture gives better results. The pure Stäcke operation is described carefully and will help to fix in the mind the difference between this operation and that one which is so often called indifferently the Stäcke or radical operation. The radical operation as practised in England is Professor Broca's operation for making a mastoid-tympanic cavity, but the former is the more complete procedure. *The author passes on to describe the* methods of operating for intracranial lesions but is less explicit and enters less into detail than in respect to mastoid operations. The last third of the work is devoted to "The Atlas," the value of which would have been much enhanced had more attention been paid to the explanations of the plates; we also think that a short index would have been an advantage. Mr. Yearsley has attempted to adhere rigidly to the author's text and in consequence the language is somewhat obscure at times

---

## LIBRARY TABLE.

*De l'Obésité.* By Dr GABRIEL LEVEN. Paris: G. Steinheil. 1901. Pp. 130 —This little *brochure* on the etiology and pathogenesis of obesity will well repay those who take the trouble to read a scientific article of this kind in a foreign language. We would particularly commend Dr. Gabriel Leven's work to those writers—and there are many of them—who venture into print on the subject of obesity. It is chiefly owing to the writings and work of Bouchard that we possess any pathology at all on the vexed question of abnormal depositions of fat in the human subject, and it is owing to the teaching of this great *savant* that his pupil, Dr. Gabriel Leven, is in a position to publish the learned and philosophic treatise which is now before us The author holds definite views on the subject of which he treats and he has made some very valuable investigations of a clinical, as well as of a laboratory, character, to support the hypothesis which he expounds. Briefly stated, the main contentions of Dr. Gabriel Leven may be summarised as follows. Obesity is a morbid symptom and not a *disease entity; it is, in fact, the outward* expression of a general disturbance of nutrition. Since nutrition is dependent on the energy liberated by the nervous system it is logical to assume that a disturbance of nutrition may be referred to a disturbance of nerve function. Clinical *evidence is strongly in favour of this view in the cases both of* localised and of generalised lipomatosis. Depositions of fat and fatty degenerations not infrequently occur as the direct result of local nerve lesion and general nervous disorders. As regards the etiology the author has collated a considerable mass of clinical evidence that dyspeptic symptoms almost invariably accompany the pathological deposition of fat. For our part, however, we cannot admit that he has established his claim *that dyspepsia* and obesity stand in the relationship of cause and effect; they may equally justly constitute pathological expressions of the same symptom-complex. A record of very carefully conducted experiments appears to prove, however, that in the case of obesity uncomplicated with renal, cardiac, or hepatic lesions, the urinary coefficients are the same as in normal conditions That obesity can occur independently of dietetic causes and of changes in the urinary coefficients is certainly a very strong argument in support of the nervous origin of this condition, at least in a very large number of cases. Intelligent and intelligible as are the arguments brought forward by the author to establish his views, we cannot help thinking that had he more carefully differentiated between the etiology and the pathogenesis he would have gained a larger following of adherents. There is something confusing in the idea that obesity is due to nerve disturbance and yet generally caused by dyspepsia. The causes of dyspepsia, according to a common-sense view, may be the same as those of obesity—namely, nervous exhaustion due to overaction of the nerve-centres which control nutrition. It is hardly possible to conceive that anything can be so effective in the determination of this condition as the prolonged intake of an excessive dietary. As we have already mentioned, Dr. Gabriel Leven's little book should be read by all who take an interest in the subject of obesity, as it reflects accurately the teaching of the Bouchard school and is not without many valuable and original suggestions.

*Pneumonia: Clinical Section.* By Sir J. W. MOORE, M.D. Dub. Reprinted from Vol. IX. of the "Encyclopædia Medica." Pp. 39 —As indicated by the title this pamphlet is a reprint from the "Encyclopædia Medica" of Sir J. W. Moore's article on Pneumonia considered purely from a clinical point of view. In accordance with modern views he considers pneumonia to be a specific general infection of bacterial origin analogous to the other infective or so-called "zymotic" diseases. A good account is given of the symptomatology of the disease, especial stress being laid on the atypical peculiarities which occur at the extremes of life In dealing with the diagnosis attention is drawn to the value of the myotatic irritability of the pectoral muscles as an early sign. Some observers (notably Dr. Kennan) claim for this sign that it

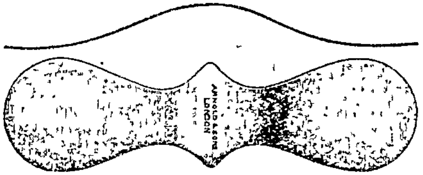
# The Edinburgh Scheme for a Psychiatric Clinique.

SCOTLAND is always to the fore in lunacy matters, and the scheme proposed by SIR JOHN SIBBALD and supported by the chief physicians of Edinburgh for promoting the treatment of early mental disease in the wards of the Royal Infirmary is not only excellent in itself but is worthy of the most careful consideration at other hospital centres. The conception is not entirely new in some of its essentials, but the Edinburgh proposal points to more complete developments than have hitherto been entertained. It proposes to apply general hospital treatment to those early cases of mental disorder where the patient cannot as yet be certified as insane, generally known as "borderland cases," but it is also to include acute insanity of a temporary nature. Of the value of treating the borderland cases in the proposed way there can be no question, but the difficulty is to get patients in this stage to offer themselves for treatment, partly because they do not always themselves recognise the condition in which they are, and partly because their friends do not know the importance of the premonitory symptoms The friends are therefore unwilling to interfere with the occupation of the bread-winner who is only, as they think, suffering from some trifling affection which will soon remedy itself.

The greatest difficulty is with the second class of persons—viz, those afflicted with acute insanity of a temporary nature It is hard to say when acute insanity is of a "temporary" nature, and this is just the class where a mistake may be made by not removing the patient at once to an asylum where he can have the special care and opportunity for outdoor treatment that few hospitals can give. Is there not a little tendency nowadays to let sentiment outrun discretion? It is quite true that, rightly or wrongly, the public does view with dislike and distrust the placing of persons in special institutions under certificates, putting the "stigma of insanity" upon them, as it is termed; but this feeling may be carried too far in the interests both of the patients and of the public, and unless the arrangements of a general hospital are more complete and elastic than is possible at most of them it will scarcely be found possible to treat acute insanity with due regard to the other inmates. It so happens that much of the acute insanity in Scotland is of the depressed or melancholic form, a kind especially suited for general hospital treatment, and if the hospitals are in touch with the asylum authorities there ought not to be any difficulty in transferring with ease and rapidity any turbulent or unsuitable cases that arise. At St. Thomas's Hospital, London, there has been for some time an out-patient department for the treatment of early mental symptoms, and the experiment, we are told, has been very successful; but let it be remembered that in bygone days insane patients were actually treated in the wards of at least one of the London hospitals, and that eventually the plan was given up as unsatisfactory. As to the value for students and for post-graduate classes of a clinique of psychiatry at a general hospital there can be no doubt. It is just in the early stages of mental aberration that the changes occur in conduct and disposition which lead to misunderstandings in families and subsequently to serious physical and moral developments, all of which might be capable of explanation and removal if the real nature of their existence was understood. There is scarcely any form of disease in which nervous symptoms of one kind or another are not present The association between neuroses and bodily states is a matter in which the student has been until lately uninstructed, but hospital physicians are now beginning to recognise the importance of the matter, as a proof of which we may mention the papers on nervous disorders now frequently read at strictly psychological associations by general physicians

A review of the prevailing practice of dealing with private insane patients points to this very striking fact that the owners of private asylums are complaining of the increasing tendency to place patients in homes or in the care of general practitioners; and there is no doubt that cases of early alienation are sent for advice to the "neurologists," and that those engaged in consulting lunacy practice rarely see people unless it has become a necessity for certification. The trend of public opinion appears thus to be confirmatory of the action of the Edinburgh physicians. If a complete development of this hospital system of early treatment becomes an accomplished fact it may have a real effect upon that burning question, in London at least, of future lunacy accommodation, for in London we appear to be running to the extreme of building beyond the necessities of the situation. It is certain that, however great the accommodation may be, there will always be found candidates to occupy it, and it is, perhaps, better to be undersupplied with lunacy accommodation than to have room always forthcoming on demand. Practical experience has established beyond question the fact that when room cannot be got it oftens turns out that it is not wanted. To apply directly to London the Edinburgh innovation is not possible because of the overcrowded state of our hospitals and because of the difficulty of securing the concerted action that is possible in a city of smaller dimensions Probably the best arrangement would be that each lecturer on mental disease—and there is already one attached to each medical school—should be appointed as physician to an out-patient department, to which all cases of early mental impairment would be referred. He would then either attend to them at his regular visits or, if necessary, advise their reception into a special hospital, for it would not be possible in London to keep a separate system of wards in the general hospitals for these cases More than this does not at present seem feasible Of course, this is carrying out only a part of the Edinburgh programme, and it is nothing more than an extension to all the hospitals of what is already done at St. Thomas's Hospital.

At the National Hospital for the Paralysed and Epileptic many borderland cases attend as out-patients, but by the operation has not been successful a second can be performed without removing the guard. The freest ventilation being allowed, the vesicles are permitted to come and go under



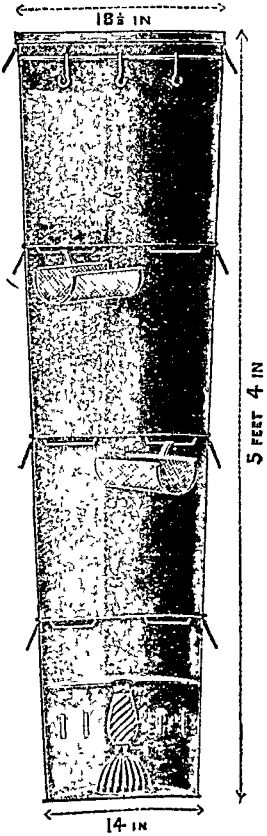
the most favourable and natural conditions, not being pressed upon or heated or sweated as they would be when smothered in cotton wool or kept under comparatively air-tight appliances

London. HAYDN BROWN, L.R C.P., L.R C.S Edin

## A PORTABLE DISINFECTOR FOR PRIVATE AND HOSPITAL USE

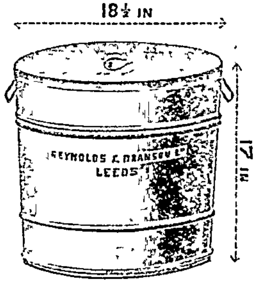
THIS apparatus, which is made of strong tin and built up in four sections (which fit inside one another for portability—see Fig. 2), is intended for disinfecting clothes, gloves, &c., after exposure to infection, and I am finding it so useful in my practice that I thought it would interest and be of similar use to others. Formalin is the disinfectant and the disinfection is carried out with little or no trouble and with no nuisance, for it can be used in a closed-up room without smell or perceptible change in the atmosphere of the room and without injury to clothes or furniture We all know the obvious disadvantage of sending clothes to be disinfected at a public disinfecting place.

FIG 1.



Apparatus open – in section

FIG 2



Apparatus closed.

The apparatus is intended to overcome this objection and will be found specially useful to medical men and nurses.

*Directions for use.*—1. Fix up the sections as shown in Fig. 1. 2 Hang up the clothes on the hooks of the rod. 3. Place smaller articles, such as gloves, &c., in the moveable racks as shown in the illustration. 4. Light the lamp and drop three formalin tablets into the receiver and slide the lamp into position (see Fig. 1).

The apparatus was skilfully made for me by Messrs. Reynolds and Branson, Limited, Leeds.

HERBERT J ROBSON, M.R.C.S. Eng., L.R.C.P. Edin.
Leeds

## PINE FIBRE FOR MATTRESSES, ETC.

FEATHER-BEDS are familiarly associated with the idea of luxury, but it has now for some years been recognised that mattresses stuffed with fibrous materials are equally comfortable and more wholesome. Horsehair has a well-established reputation as perhaps the best of these substances, and although it has competitors it is not likely to be superseded Another stuffing for mattresses, which is novel in this country, but is said to have been well tested in America, has been submitted to us by a firm of bedding manufacturers trading as Davis's Feather Mills, Limited, 61, 62, and 63, High-street, Whitechapel, London, E It is prepared from the long tufted foliage of the *Pinus australis*, the Georgia pitch-pine, or yellow pine of the southern portion of the United States The finished product to which the name of pine fibre has been given consists of tough, interlacing, flexible fibres, rather stouter than horsehair, curling naturally and averaging from six to eight inches in length and upwards. When in quantity it forms an open, porous mass, freely permeable to air, elastic, soft, and springy to the touch, and to all appearance admirably fitted for use as a stuffing for mattresses or cushions. It is of a dark-brown, somewhat glossy colour, possesses a slight odour somewhat resembling that of fresh pine-wood sawdust, and by reason of its vegetable origin will no doubt be free from any tendency to attract moths which are so destructive to hair or wool stuffings The makers state that the fibres do not break up or become lumpy, and that mattresses filled with this material have been in use for many years without sensible deterioration The fibre may be obtained either made up into mattresses, bolsters, or pillows, or in bales averaging about 2 cwt each

WESTERN DISPENSARY, BATH —The annual meeting of the subscribers to this institution was held on Jan 24th, under the presidency of the mayor (Mr. E. E. Phillips, M.R.C S Eng , L.R.C P. Edin , J P.) The financial statement was satisfactory and showed a favourable balance of £55. The medical report stated that during 1901 there had been 876 cases treated and 434 patients had been attended at their own homes can be kept apart from the other inmates of the dwelling, few discreet medical officers of health would care to force the situation to a legal decision unless a member of the household were concerned in the distribution of some article of food-supply such as milk. In a case of scarlet fever very similar arguments would have weight, but the presence of children at school ages, as also the carrying on of a business such as that of a dairy, would at once render home treatment unsafe, and it would always be wise in the case of scarlet fever to set apart two rooms for the use of the patient and the attendant. In short, the occupation and age-distribution of the invaded household must to a very material extent govern the decision to be arrived at. In dealing with small-pox we are face to face with a disease which possesses not only a very high degree of infectivity but also a fatality-rate of somewhat alarming proportions. Moreover, the disease, even when it does not kill, is liable to lead to serious disfigurement, and hence it is shunned in a manner which is certainly unique among our more or less endemic diseases. Small-pox, too, is perhaps the best type which we possess of what may be called air-borne diseases, and it possesses an attacking power not found in the case of any other infectious malady. Aerial convection is doubtless operative in some degree in several communicable diseases, but the evidence with respect to the resistance and viability of the small-pox virus is such as to place it almost in a class by itself. For these reasons the removal of all cases of small-pox to an isolation hospital specially set apart for the segregation of that disease is eminently desirable, and there are very few instances, more particularly under urban conditions, where the medical officer of health would care to accept the responsibility of allowing a patient with this disease to remain at home. Still, it would be altogether straining the position to assume that a case of small-pox must of necessity be removed in every instance. In a detached house where, perhaps, a whole floor or even a wing of the building could be devoted to the patient and his attendant, where money was practically no object, and where the householder was prepared to carry out all the suggestions of the medical attendant and the medical officer of health, it would, it seems to us, be unwise in the best interests of the public health service to *insist* upon the removal of such a patient to a general small-pox hospital. In the case of the modern blocks of buildings known as "flats," where there is often direct aerial communication between one suite and another, either by means of the staircase, the lifts, or the dust-shoot, it would appear to be very questionable if the patient could be regarded as having proper accommodation within the meaning of the Public Health Acts

It is, of course, much to be regretted that every town is not as well provided with hospital accommodation as is the case in the metropolis, where both public and private accommodation is available. If the medical officer of health can tell the relatives of the patient that a special ward will be provided he is, under certain conditions, in a far stronger position to insist upon removal than would be the case were he aware that the patient must be housed in the general ward with people occupying a much lower social and educational plane. Fortunately the educated classes are now learning to get themselves revaccinated at intervals, more particularly when small-pox threatens to prevail, and the more this custom obtains the less likely to arise are the difficulties as to isolation to which we have here drawn attention.

◆

# The National Hospital for the Paralysed and Epileptic.

THE medical staff of the National Hospital for the Paralysed and Epileptic are to be congratulated by the whole medical profession, and by all who are interested in the welfare of the hospital, on the happy result of their long and arduous struggle. This struggle, as our readers may remember, owed its commencement to the repeated refusal of the Board of Management of the hospital to allow the staff a very modest representation on that Board. The staff, despairing of redress from the Board, finally addressed themselves to the governors and brought forward instances of bad management and of defects in the diet and nursing of patients which ought never to have occurred in any well-ordered institution. They appealed to the governors to institute a thorough and searching inquiry into these matters and also into the whole management and constitution of the charity. It is needless to recapitulate the various devices to which the Board resorted in its attempts to evade such a demand Fortunately, after much time had been consumed in fruitless negotiations and prolonged newspaper controversy, the governors took the matter up energetically and appointed some of their own number to choose a committee consisting of legal, medical, and business men, to investigate the charges brought forward by the staff. This committee was appointed both to inquire into the general constitution of the hospital and into the position and acts of the secretary-director—an official created by the Board apparently to act as its delegate and one of whose functi seems to have been to keep the Board and the staff fi directly communicating one with the other. This c mittee was presided over by Sir EDWARD FRY, and recommended, amongst other things, that the staff sho have the representation on the Board for which they ha long contended, and that the office of secretary-dire should be abolished. Incidentally the report of the c mittee showed considerable remissness on the part of Board in carrying out the duties entrusted to it by rules, and that body did not escape censure for the appro and support which it had furnished to the secretary-direc in his autocratic dealings with the medical staff.

The immediate result of this report was that the secreta director resigned his office. It was a matter for surprise many people who had read the report that the Board not follow his good and proper example. At the meet of governors called to receive the report a commit containing representatives of the Board, the medical st and the governors, was appointed to frame a body rules giving effect to the recommendations of EDWARD FRY'S committee. These rules were next submit for adoption to a meeting of governors. An adverse propo was made by a member of the Board, who attempted get the four other votes necessary to take a ballot of whole body of governors, but the attempt failed and the ru rules of the hospital they cannot be admitted inside the wards, and so they are either relieved as far as possible or are sent to the authorities who certify them for asylums In most out-patient departments cases of this sort at times present themselves, and if the London hospitals possessed such an annexe to their work these patients could be drafted to the psychiatry department It is under the consideration of the London County Council to procure authority for the erection of "reception houses" for early cases of mental disease. The "reception houses" will be in the nature of hospitals where such patients may be kept until it is seen whether they are likely to recover in a short time or whether it is advisable to have them placed under certificates and sent to an asylum. To our mind, these "reception houses" form the solution of the difficulty, and we advise the authorities in Scotland to consider this plan before finally determining to use the general wards of the infirmary for acute cases of temporary insanity, or even borderland cases. The system of "reception houses" seems an ideal one, for it does away at once with the slur on the patient of having been in an asylum and it brings the general hospitals into direct *rapport* with the means of treating the cases which cannot with advantage be left at home It was the expense and the moral cruelty of sending to an asylum these early cases which only required a few days' care that led to the suggestion of receiving houses, which, perhaps would better be termed "hospitals," the words "asylum" and "certificate" being reserved for other cases. To proceed with the erection of these reception houses it is, we believe, necessary to have some legislation, and we sincerely hope that if it is necessary a new Bill drafted in a very liberal spirit will soon be brought forward and carried through When these new buildings are erected it is eminently desirable that they should be conducted upon the most advanced medical lines, with a due regard to the object of using them as places for clinical study and research. To carry out this object there should be a complete visiting medical staff, and no obstacle should be allowed to stand between the intimate relation of the institutions to the general hospitals which would act as feeders to them, while greatly relieving the strain on their resources. For general hospitals would then be spared having to treat cases of delirium tremens or early alcoholic insanity, to say nothing of other cases which at present cause much noise and inconvenience. If the sites of the proposed houses are well chosen the alliance with the hospitals should be complete, and the system of treatment of acute mental disease generally will in London be placed on a very satisfactory footing.

It is noticeable that in Scotland the scheme of the hospital treatment of acute mental disturbance was brought forward by a former Commissioner in Lunacy. It has not hitherto been the custom in this country for the Commissioners in Lunacy to pose as pioneers in the direction of lunacy reform their functions being apparently to see that the law as already expressed is carried out properly; but surely this is a matter in which we may fairly hope for some initiative from so experienced a body as the Lunacy Commission. In many particulars, such, for example, as the choice of site or form of asylum, public bodies are left to flounder without any aid from those who have the real opportunities of seeing all that is best and worst in the country. It is to be hoped that the influence and authority of the Commissioners in Lunacy may be brought privately to bear, if it is not thought advisable for them to act openly, in evolving a scheme which will allay the apprehensions of the public. It is necessary to bring mental diseases into line with other general diseases, whilst at the same time providing an opportunity for clinical teaching on the subject, the absence of which to-day is rather a cause of reproach The eyes of the medical world are at present upon what is being done in London towards attaining to the best form of treating mental disease, and we have already had occasion to point out some improvements which have been recently effected and which have been copied. The establishment of a system of combined treatment of mental and general diseases would most probably soon have imitators in the large provincial centres where the whole subject of the treatment of mental disease is also a very pressing one

# What is Proper Isolation Accommodation?

WITH the prevalence of small-pox the question of what is proper isolation may at any moment present itself in a somewhat inconvenient fashion, and hence it may be useful to discuss some of the phases that the problem is not unlikely to assume Fortunately the case of WARWICK *v.* GRAHAM, to which we referred last week (p. 241), has established the proposition that although a person suffering from a dangerous infectious disorder may have proper lodging and accommodation in so far as he himself is concerned he is, nevertheless, "without proper lodging and accommodation" within the meaning of Section 124 of the Public Health Act, 1875, and Section 66 of the Public Health (London) Act, 1891, in the event of his being a danger to his fellow creatures. The question therefore resolves itself largely into a matter of opinion on the part of the medical officer of health, and what may be feasible in the case of one disease is impracticable in the case of another. In a problem of this nature mathematical precision cannot be arrived at and due regard must therefore be paid to the relativity of the situation. In deciding what attitude he shall adopt in any specific instance, the degree of infectivity and the fatality-rate of the disease with which he has to deal must largely govern the actions of the medical officer of health. It might obviously be contended by an extremist that nothing short of isolation in hospital would meet the requirements, but such an extremist would find it difficult to establish the position that even isolation of this character was absolute There are few, however, who would reduce things to such an absurdity, and the medical officer of health will be found as a rule to take a reasonable view.

Assuming, for instance, enteric fever to be in question the prevailing opinion would probably be that in the homes of the poor, where the patient cannot be accorded the sole tenancy of an apartment, and where detailed supervision as regards nursing is impracticable, the necessities of the situation demand the patient's removal to hospital If, however, skilled nursing can be afforded and the patient of days spent by its shores and of work he did there in anthropology. Addresses also came from Zürich, Basel, and Berne. England, Scotland, and Ireland sent delegates and addresses, with Lord LISTER at the head of the first. From Italy came BACCELLI with a gift from his Government and the diploma of doctor from the medical faculty of Rome. Scandinavia, Finland, France, Belgium, Holland, and Russia were all represented, and he specially refers to Japan, whence many pupils have come to him and whence, he trusts, the methods of modern science will spread over the Far East. Then he speaks of Germany and tells how gifts and honours were showered upon him from the KAISER downwards. For all these exceptional honours he can, he says, do nothing else than repeat his heartfelt thanks. He is too old to promise any new performances worthy to be regarded as a return for such gifts; but he goes on to say, "I shall not weary of work so long as my strength shall last" He cannot expect to do more than bring to a fitting close labours commenced in his earlier years. The wonderful reception he had seems to have touched him deeply, and he relates how all the people seemed to share in it. For, he says, "when on returning home quite late from one of the *fêtes* I found my little street illuminated throughout," and he had to pass through ranks of children whose welcome followed him to his door; and daily as he passed along the street children would greet him with outstretched hands and a "Good day, Herr VIRCHOW." It is characteristic of the man and his wide sympathies that he should reckon as the most striking event of those stirring days the reception given to him by the Mechanics' Union which he himself had founded and in the work of which the late Emperor (then Crown Prince) FREDERICK and his gracious consort were deeply and personally interested. This body has given rise to numerous similar associations in all parts of Germany, and although many of these have been destroyed by the spread of Socialism the Berlin organisation remains. At the banquet which the members of the union gave him he says "the old songs were sung, once more I made them a speech, and hands were stretched out to me just like those of the children of the Schelling-strasse. It was the expression of the people's gratitude, and therefore I may say to everyone, Trust the people and work for them and you will not fail of reward, although the breaking up of many systems, the disappearance of many men, the complete transformation of public life, bring home to us the thought of our own evanescence. That is my confession of faith, and with this I hope to be guided so long as I live."

We have summarised this message which Professor VIRCHOW has sent forth to his friends in all parts of the world in order that we may gather therefrom the inspiration which has been his leading principle throughout life. He has shown how devotion to science in many fields is not incompatible with taking a prominent part in the practical life of the community and the promulgation of ideas for the bettering of mankind. He has never wearied of well-doing, and the multifariousness of his interests, as well as the singular simplicity of his aims, have made him to-day the most striking figure of his time. If the article we have dealt with may seem tinged with egotism, it is, we may be sure, not the conscious egotism of vanity, but that which springs naturally to the front when, surveying the experiences of a long and busy life, a man tells his friends of the part he has played in history. That the life of one who has accomplished so much in his day, and who deserves all the honours that have been bestowed upon him, may be prolonged to see the fulfilment of his projects is the fervent hope of all who have learnt to know and to appreciate his labours.

# Annotations.

"Ne quid nimis."

## THE ETIOLOGY AND TREATMENT OF CANCER.

IN the present number of THE LANCET we publish a case of cancer of the uterus treated by Professor Albert Adamkiewicz by injections of cancroin in which there occurred marked retrogression of the disease and a great improvement in the condition of the patient. Professor Adamkiewicz holds the view that cancer is the result of the action of parasites and he thinks that the poison produced by the growth of these bodies should be of value in arresting the progress of the disease. For this purpose, as the result of investigations carried out upon the poisonous products, he injects a substance which he terms "cancroin." This body appears to be chemically equivalent to neurin—that is to say, it is trimethyl-vinyl-ammonium-hydroxide. Professor Adamkiewicz uses a 25 per cent. solution neutralised with citric acid, saturated with phenol, and mixed with twice its quantity of water. His original observations and experiments were published as far back as 1893. It is curious, if the method is capable of giving such good results, that it appears to have been employed in so few cases by other surgeons and that we have heard comparatively little about it during the last eight years. For these reasons, although the present recorded case is undoubtedly a striking one, yet we are inclined to be a little sceptical as to the results to be obtained by a more extended use of this remedy. In THE LANCET of Jan. 11th (p. 126) our Paris Correspondent called attention to the paper submitted by Dr. Doyen to the French Academy o Medicine. Dr. Doyen announced the constant presence o a new microbe in cancerous tumours, a microbe which h had been able to isolate and to cultivate. It occurs in th form of motile diplococci which can be cultivated in tube of gelatin and gelose with the addition of a specia bouillon. The organism appears to be more easily found in the affected glands and secondary growths than in the primary tumour, and has been found in th blood itself. The ease with which cultivation can b obtained appears to vary directly with the malignancy of th growth. Subcutaneous injections of the toxin of thi microbe attenuated in some special manner brings about especially in the glands, a reaction similar to that produced in tuberculous glands by the injection of Koch's tuberculin Post-operative injections of the toxin appear to have given good results which have endured for six months, but further observations are necessary upon this and other points It will be interesting to hear whether the toxin of Dr. Doyen had any relationship to the "cancroin" of Professor Adamkiewicz. The view that cancer is primarily a disease of the epithelium is gradually gaining ground, but, so far the weight of evidence has appeared to be against the parasitic theory. It is possible that a considerable gain to our knowledge may result from the work of the commission which the German Government has appointed to consider the whole question. A very graceful compliment has been paid to British workers and pathologists by the appointment were adopted with only verbal alterations. These rules necessitated an election of a Board at an early subsequent meeting. This election was held on Jan. 9th and the two medical representatives having been already chosen by the staff 10 vacancies remained to be filled up. For these vacancies 10 names were proposed, and two members of the old Board sought re-election On a show of hands the latter were rejected, but a ballot was demanded on their behalf and the result of this ballot was declared at the meeting held on Jan 23rd It need only be said that the result of the ballot confirmed the vote of the previous meeting, the governors clearly indicating their determination no longer to utilise the services of any of the old Board of Management who had in their opinion endangered the very existence of the charity.

The hospital may now be regarded as "swept and garnished." It cannot be denied that much hard and energetic work lies before the new Board. In this it will be cordially and loyally assisted by the medical staff and, we doubt not, by the general body of governors. Everyone interested in the hospital must now feel that at last it is established on a broad basis, which will give it strength and stability and will enable it to extend its already large sphere of usefulness, not only in the cure and relief of suffering, but also in the acquisition and dissemination of medical knowledge.

# Professor Virchow's Message.

THE current number of *Virchow's Archiv*—the first part of the 167th volume—opens with an article by its venerable editor which cannot fail to awaken sympathetic interest at the present time when he is lying on a bed of sickness. It is addressed to "my friends" and is intended to convey to them collectively, since it was impossible to do so individually, his thanks for the share which they took in celebrating his eightieth birthday on Oct. 13th, 1901. He chose for this purpose "this old *Archiv* which for more than 50 years has been the medium for our mutual explanations" He says that his scruples against any such celebration were over-borne by his friends, so that he had to submit passively to their plans "like a patient in the hands of his physician," and he mentions with gratitude the kind services rendered to secure the success of the *fête* by Professor WALDEYER and Professor POSNER. The celebration took place—delegates and addresses flowed in; of telegrams alone he received 800; messages and gifts came from all parts of the world, especially from bodies concerned in subjects in which this many-sided man had interested himself, not only medicine and natural science, but also anthropology, archæology, literature, philosophy, and social science. He recalls how the sphere of his activities was first widened when in 1848 he was directed to investigate the causes of an outbreak of famine fever in Upper Silesia. He found that social imperfections were at the root of such evils, and he determined henceforth to press for reforms in this direction. Like experiences followed his acquaintance with similar outbreaks in Bavaria and Prussia, and he adds that it was in his wards at the Charité that his assistant OBERMEIER made his fruitful discovery of the spirillum of famine fever. These and other epidemic plagues convinced him that practical medicine was intimately bound up with social legislation and he preached this doctrine in the pages of *Medicinische Reform* in 1848-49. Since then, he says, hygiene has become a public duty and for a physician to be also a politician is no longer a reproach. Even yet he thinks the value of medicine in matters of the common weal is not fully recognised. He goes on to speak of his early inquiries into mortality from phthisis at Würzburg which set him on to prolonged study of the nature of tuberculosis and its relationship to phthisis. He described *Perlsucht* (bovine tuberculosis) and pointed out its differences from human tuberculosis, and although his descriptions did not prevent that affection from being termed tuberculosis and even regarded as a prime source of the human disease, yet in these latter days the question of their non-identity has been raised by Professor KOCH himself. Professor VIRCHOW rather caustically adds that this ought to be taken as a warning not to confound causes of disease with their nature (*Wesen*) by neglecting pathological anatomy.

He then alludes to the great sanitary advances which he has seen, and refers with manifest pride to the fact that as town councillor of Berlin for well-nigh 50 years he has shared in the task of improving the dwellings of that city and of converting it into one of the cleanest and most beautiful as well as the most healthy of great towns. This has only been done at vast expenditure, but the cost has been repaid in gain of health and life. He refers to other directions in which science has contributed to the public health and cites the regulation of the supply and inspection of meat, recalling the opposition which had to be overcome when such measures were set on foot, as, for instance, in the prevention of trichinosis, remarking that it came from those who with but half knowledge think that they can set aside the results of expert investigation This mention of his connexion with the municipal life of Berlin seems to recall to him other civic recognition that he has received. Bologna, the oldest university town of Italy, like Berlin, has enrolled him on the list of its honorary citizens, whilst streets have been called after him in Nuremberg and Wurzburg, and he mentions with great satisfaction that the new hospital in Berlin has received his name. Nor was his birthday forgotten by the inhabitants of the village of Virchow in Lower Pomerania, who sent an address mindful of the visit he had paid many years ago to show his sons this place. This personal recognition by communities has given him great pleasure, for they came unsought and without any other end to serve than personal homage He goes on to sketch briefly the special addresses and other marks of esteem for his scientific labours which the occasion of his birthday brought him. It is not possible to give them all here, and besides in the article itself he is only able to deal with them very summarily. There was a collective gift from the scientific and medical societies of Austria—a casket containing 80 special addresses The presentation was made by Professor TOLDT, and it will be a precious remembrance. There was also a collective address of Australian physicians, perhaps the first occasion in which a whole continent had united to send its greeting and testify to its common interest in general science. From Switzerland came an oil painting of the Walensee, a precious memento their small thefts are condoned or if presents of food are left out for them they will take them away at night and make a return by leaving skins or ivory. Occasionally they steal the children of other tribes and leave their own changelings in place of those stolen. Dwarf women marry men of the big races, but Sir Harry Johnstone does not mention the converse as happening, although folk tales are full of stories of women of the upper world being carried away by the dwarfs of the underworld. We have not space to pursue this subject further, but the curious reader will find a most interesting note appended to the version of "Childe Rowland" as given by Mr. Joseph Jacobs in his "English Fairy Tales."

## THE PAY OF CIVIL SURGEONS SERVING WITH THE ARMY AT HOME.

In our issue of Dec. 7th, 1901, p. 1598, we referred to the matter of the pay of civil surgeons serving with the army at home. The chief point upon which we commented was the refusal of the Secretary of State for War to allow the civil surgeons the gratuity specified in Army Order 136 of June, 1901. We now hear that the civil surgeons interested have received a reply on behalf of the Secretary of State for War to the effect that he has given full consideration to the claims of the civil surgeons for increase of salary and payment of gratuity but that he is unable to grant either So, we suppose, the matter rests, but we confess that we should like to know how Mr. Brodrick squares this decision with Army Order 136. True, the Order was only to apply to surgeons whom the Secretary of State for War considered eligible, but are none of the civil surgeons eligible?

## THE MANAGEMENT OF REFORMATORY AND INDUSTRIAL SCHOOLS.

Mr Edric Bayley, L C C, has embodied in a careful and instructive paper certain suggestions for the management of the London Reformatory and Industrial Schools. At the present time these schools are administered by three distinct authorities The Corporation of the City of London is responsible for 81 children in the city committed to reformatory or industrial schools, at an average cost of £16 17*s* 3½*d.* per head. The corporation has no schools under its own control but pays for the accommodation of these children in schools under other management. The School Board for London has an interest in the ordinary industrial schools in the county of London outside the city and in truant schools and day industrial schools established under special enactments both within and outside the city. It has no concern with reformatory schools It provides, partly in schools under its own direction and partly in other schools with which it has made arrangement, for 3945 children, at an average cost per head of £12 18*s.* 7¾*d.* The London County Council has under its charge in reformatory schools and industrial schools outside the city, but in the county of London, 1115 children, at an average cost of £18 12*s.* 2¼*d* per head It has also made provision for the further training and employment of boys by creating homes at Llandilo (Carmarthen), at Cardiff, and at Lowestoft, where the pupils are employed in farming or are enabled to follow a trade or a seafaring life It finds occupation for others in its own works department and makes arrangements with technical institutes to receive boys for instruction after leaving school. The greater cost per head of children under the supervision of the Council is largely due to the fact that two large industrial schools under its control at Feltham and Mayford receive a much less number of inmates than they are capable of accommodating. Consequently their expenditure is relatively high as compared with the educational work which they are allowed to do. This disproportion would be remedied with mutual benefit, both as regards economy and educational advantage, if suitable pupils under the care of the London School Board were consigned to the establishments under the control of the London County Council. Both of these bodies are supported by the same rate-paying constituency and they have not so far been organised so as to supplement one another and thus to husband the finances of both in the most efficient manner. This, in brief, is Mr. Bayley's argument, and he proposes in support of it that a joint committee should be formed representing these two now separate authorities with the object of enabling them to act in unison. He suggests also that the Corporation of the City of London, in so far as it is concerned with education, should be affiliated with them, and that the Poor-law authorities in London, who are responsible for the training of 18,000 children, should enjoy the same privilege in respect of refractory cases for which the discipline of industrial and reformatory schools is advisable. It must be admitted that there is a good deal to be said in favour of this proposal and there is no doubt that throughout his interesting paper Mr. Bayley has followed with commendable impartiality the logic of the facts on which his argument is based.

## THE TRANSMISSION AND PROPHYLAXIS OF MALARIA.

In an article which originally appeared in the *Giornale Medico del Re Esercito* for March, 1901, and which the writer has now republished in separate form, Lieutenant-Colonel Luigi Ferrero de Cavallerleone, director of the military hospital at Rome, gives an interesting account of a series of experiments which was carried out under his orders during the autumn of 1900 in order to elucidate as clearly as possible the rôle played by the anopheles in the transmission of malaria and at the same time once more to demonstrate the prophylactic virtues of quinine. Six of the most malarious forts on the Campagna having been placed, together with their garrisons, at his disposal by the authorities, Lieutenant-Colonel de Cavallerleone caused them to be fitted up according to his directions and issued detailed instructions for the occupants which were to be supervised and enforced by two specially selected medical officers. The investigation, which lasted for four and a half months, from July 15th to the end of November, was most strictly controlled, the results, briefly stated, being as follows: (1) soldiers protected against mosquito bites but not taking quinine, percentage of malaria cases 2·6; (2) soldiers protected and also taking quinine daily in doses of three grains, percentage of cases 1·7; (3) permanent residents, unprotected and not taking quinine, percentage of cases 33·3; and (4) permanent residents, unprotected but taking quinine daily, percentage of cases 20·0. Among 40 officers who were unprotected and took no quinine there was one case of malaria only, but in Lieutenant-Colonel de Cavallerleone's opinion this comparative immunity was due in the first place to a short period of residence (eight days on an average) and, secondly, to the fact that officers are far more cleanly in their habits than are private soldiers and consume more nourishing food. Among 1632 soldiers garrisoning the forts which were not included in the experiment the percentage of cases of malaria was 0·5 These men were not specially protected against mosquitoes but they all took quinine daily. In five out of the six forts where the experiment took place numerous specimens of the anopheles were captured and the same insect was also observed in four of the outside forts where cases of malaria occurred. In the forts, however, where malaria was unknown, not a single member of the species could be detected although mosquitoes belonging to other families were abundant. In conclusion, Lieutenant-Colonel de Cavallerleone discusses various products which have been of Mr. H. G. Plimmer to serve as a member of this commission. Quite recently a movement has been set on foot in this country to raise a sum of money sufficient when invested for the interest to pay the expenses of an investigation into the whole question of cancer. The scheme has received the approval of the Royal College of Surgeons of England and of the Royal College of Physicians of London, and the only thing needed to render it successful is the money. In view of the enormous benefits that would ensue to thousands of unfortunate sufferers if any certain cure for cancer could be discovered we have great hopes that such an appeal will not be allowed to go unanswered. When so much activity is displayed with regard to the solution of the problems connected with cancer not only in Germany and in this country but also in many other countries, the beginning of the new century may well see most important advances in our knowledge of the etiology and the treatment of this dread disease.

## THE THINGOE GUARDIANS AND THEIR MEDICAL OFFICER.

WHEN dealing with a forlorn hope at the bar of justice it is not an altogether unknown practice to endeavour to conceal the weakness of the position by abusing the opposing counsel, and it would seem that amongst boards of guardians and rural district councillors there is a general understanding that when difficulties and doubts assail them the wisest course to pursue is to abuse the medical officer. An instance of this practice occurred recently at a meeting of the Thingoe Board of Guardians, and the facts are worth recalling as an illustration of the unfair positions in which medical officers are placed at times. A tramp was admitted into the casual ward of the Thingoe Workhouse on the night of Jan. 7th, and as he was not feeling well on the following day the medical officer was asked to see him. The patient presented no very definite symptoms, but as on the next day he was found to be suffering from bronchitis he was removed to the proper place—i.e., the infirmary. Unfortunately, however, on Jan. 10th the patient developed a rash which was thought to be measles and he was isolated at once, but the rash becoming vesicular small-pox was recognised and all precautions against the spread of the disease were taken. As far as we are able to judge from the reports which have reached us, the medical officer acted properly and with commendable promptitude, but the chairman of the board of guardians, as also a non-medical Local Government Board inspector, thought otherwise. In their view the patient should at once have been sent to the isolation block and not to the infirmary, and the inspector went so far as to characterise the medical officer's action as "most reprehensible." It is to be deplored that in matters such as this a lay inspector should be in a position to make derogatory comments upon the conduct of a medical man in connexion with a question concerning which such inspector cannot possess the necessary training or knowledge to form a correct judgment upon. It is easier to be wise after the event than it is to diagnose a case of small-pox when all the data necessary for arriving at a conclusion are absent. To send a patient who was apparently suffering from bronchitis alone into an isolation block would, it seems to us, be most unwise, and we would remind the inspector, as also the chairman, that small-pox does not usually begin with bronchitis. The chairman stated at the meeting that small-pox "would have been the first thing which would have struck him," but if all tramps who present themselves at the Thingoe Workhouse, and who are unfortunate enough to be suffering from bronchial catarrh, are to be sent to the isolation block to keep company with the small-pox patient we trust that the chairman will persuade them to be revaccinated on arrival. Had the Local Government Board inspector taken the precaution to consult one of his professional colleagues he would doubtless have omitted his uncalled-for comments, but all this is a likely consequence of the employment of lay inspectors to deal with scientific matters. Now that a case of small-pox has actually occurred the guardians have resolved to purchase a wooden hut, and from this it is to be inferred that the Rural District Council of Thingoe has failed to provide the necessary isolation accommodation for small-pox, a reprehensible omission which does not seem to have called forth any criticism from the Local Government Board inspector.

## SMALL-POX IN LONDON.

THE returns of small-pox in London for the past week show the following figures. On Saturday, Jan 25th, there were 28 fresh cases notified and removed; on Sunday, the 26th, there were 23 fresh cases; on Monday, the 27th, there were 53 fresh cases; on Tuesday, the 28th, there were 58 fresh cases; and on Wednesday, the 29th, there were 71 fresh cases.

## EXPERIMENTS UPON THE CAUSE OF SUDDEN DEATH DURING THE ADMINISTRATION OF CHLOROFORM.

WE understand that Professor C. J. Martin of Melbourne will bring forward at the next meeting of the Society of Anæsthetists, on Friday, Feb 7th, at 20, Hanover-square, W., a highly interesting communication illustrated by lantern-slide demonstration. Dr. E. H. Embley of Melbourne has, with Professor Martin's assistance, been investigating the effect produced by vagus stimulation during chloroform narcosis. All medical men are invited to be present.

## PYGMIES OF THE CONGO FOREST.

THE February number of the *Pall Mall Magazine* contains a most interesting article by Sir Harry Johnstone, K.C.B., upon ape-like men and pygmies of the Uganda borderland. The average height of a male pygmy is four feet seven inches, and of a female four feet two inches. They are of two types, a red and a black. In many the fœtal down is persistent, while in addition there is a fairly thick growth of coarse black curly hair in the usual situations such as the axillæ, the pubes, and the chest. They are of an ape-like type, the nose being very flattened, while the alæ nasi spread out and project as far as the tip of the nose. Sir Harry Johnstone says: "In some of the dwarfs there is a great prominence in the nates or posterior which recalls, though it does not equal, the huge development in that direction of the Bushman and Hottentot. This feature in man is not a particularly simian sign, as the great apes are noted on the other hand for the very poor development of these hinder muscles." Sir Harry Johnstone is arguing here from mistaken premisses: the prominence of the buttocks in Hottentots and in some other races is due not to muscular hypertrophy but to enormous masses of subcutaneous fat. In the Hottentot Venus, "Dr. Somerville found on dissection that the size of the buttocks arose from a vast mass of fat interposed between the skin and the muscles, and that it equalled four fingers' breadth in thickness."[1] Sir Harry Johnstone is, of course, struck by the possibility that these pygmies and the like races which inhabited Europe at one time are the source of all the stories about gnomes, fairies, elves, brownies, pixies, and the like. The Congo pygmies, he says, can be good or bad neighbours to their black neighbours of a larger growth according to the treatment they receive. If in the East End of London, where some ill-feeling was caused by the importation of a large number of German workmen who were provided with dwellings at a nominal rent by the employers, the latter finding this the only practical means of introducing modern methods into an ancient trade. The report contains a good deal of information which will be new to most English readers, and it is pleasing to note that there is no doubt that the conditions of labour in Russia are in many respects improving, that the number of child-workers is diminishing, and that provision is now made for their education.

---

## THERAPEUTIC APPLICATIONS OF SPERMIN.

WE have received from Dr. G. von Hirsch of St. Petersburg a short communication on the therapeutic applications of spermin, a substance of animal origin first obtained by Professor Poehl, whose investigations were published in the Russian journal *Vratch*, 1892, No 21, and in the *Deutsche Medicinische Wochenschrift*, 1892, No 49. Dr. von Hirsch's article, which is a reprint from the Transactions of the Congress of Internal Medicine held in Berlin last year, is devoted principally to abnormalities in the frequency and rhythm of the pulse and their treatment by means of spermin; it also gives references to a series of cases of anæmia, tabes, and endarteritis obliterans treated by him with the same substance and already published in the *St. Petersburger Medicinische Wochenschrift*, No. 7, 1897. Spermin is given in the form of an "essentia" of which 20 drops are taken three times a day. Dr. von Hirsch quotes numerous favourable opinions regarding it expressed by various eminent medical authorities He says that its power of correcting irregular action of the heart depends on the fact that it is an active promoter of physiological tissue oxidation, especially in the case of neurin, xanthin, and other metabolic products which act as cardiac poisons but are by oxidation converted into inactive compounds

## THE ADVANCE OF NOSOLOGY.

THE first issue for 1902 of the Registrar-General's "Weekly Return of Births and Deaths in London and Seventy-four other Great Towns" prints certain old-established "causes of death" in italics on the ground that they are "the names of symptoms only" or are otherwise objectionable Medical men are thus warned against using in future such misleading terms as "tabes mesenterica" and the familiar "convulsions," "apoplexy," and "phthisis." Nosology becomes more and more scientific, and a stroke of the pen now bids fair to render obsolete much of the terminology, not only of extant medical literature, but of familiar conversation and popular fiction when these deal with disease. The names of illnesses used at different epochs and stereotyped in bills of mortality throw a flood of light upon manners and popular opinions Referring at random to a volume of the *Annual Register* for 1783 we find that "A General Bill of all the Christenings and Burials" in London from December, 1782, to December, 1783, contains the very epitome of a past which, though not far distant in point of time, yet differs widely from our own accurate and analytical present. Over 19,000 persons died in London in 1782–83, and of these, we are informed, more than 12,000 died from old age or "aged." By "apoplexy and sudden" 219 were carried off, 19 died "bed-ridden," three died from "bleeding," five from "bloody flux," and five were "bursten." "Cholic, gripes, twisting of the guts" carried off 37. "Spotted fever, purples, flux and strangury," "headach," "headmouldshot, horshoehead, and water in the head," "imposthume," "lethargy," "livergrown"—all figure as causes of death. "Tympany," "rising of the lights," and "scald head" claim no victims, and may be survivals of an older nomenclature like our own "tabes mesenterica," but, on the other hand, "St. Anthony's fire" has one death to its account, and "grief" as many as four. It is curious to find "canker" and "cancer" already differentiated, while "phthisick and asthma" are lumped together. "Evil" still figures in place of "scrofula," now disappearing in the larger category of "tuberculosis," and we are reminded that in this year (1783) old Dr. Johnson was still manfully battling with encroaching disease, and that he was one of the last people to have been "touched" by Queen Anne for the cure of king's evil. In remarkable contrast to this semi-barbarous bill of mortality are Johnson's lines "On the Death of Dr. Robert Levet" which appear in the same volume of the *Annual Register*:—

> "Well tried through many a varying year,
> See Levet to the grave descend;
> Officious, innocent, sincere,
> Of ev'ry friendless name the friend."

Among familiar names of disease we find, in this old account of London's deaths, that small-pox claimed about one in 12 of all persons dying in 1782–83, and that consumption and convulsions swept off more than half the 19,000 who actually died. 269 individuals perished by violence or casualty, and of these 15 were executed during the year, four were murdered, 110 were drowned, while others were overlaid, scalded, smothered, burnt, or carried off by "excessive drinking." The minute description of the cause of death in these latter cases suggests social horrors of more than Hogarthian intensity.

## THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Mauritius received at the Colonial Office on Jan. 24th states that for the week ending Jan. 23rd there were 14 cases of bubonic plague, of which 7 proved fatal.—The Local Government Board for Scotland has issued a memorandum with respect to plague, dealing chiefly with the matter of rats and the chances of infection by these animals. It is pointed out that every measure should be taken to prevent rats from leaving a ship which may reasonably be supposed to be infected with plague or on board of which exceptional sickness has been prevalent among rats, even although the ship has not come from an infected port and has had no cases of suspicious sickness among her crew. All rats on board should be destroyed, their bodies being at once cremated *Pari passu*, if sickness occurs amongst rats on land measu should be taken for the destruction of the survivors, preventing their entrance into houses or ships, and as far possible all places or articles that have been exposed infection should be disinfected. As regards Egypt, duri the week ending Jan. 19th, 17 cases and 14 deaths fr plague have been announced; these all occurred among native population.

## THE VOLUNTARY NOTIFICATION OF TUBERCULOSIS.

THE Committee of the London Reform Union at its l meeting unanimously passed the following resolution:—

> That the Executive Committee of the London Reform Union, recog ing the important part which a system of voluntary notification m play in the war against consumption which the people of this coun under the leadership of the King have entered upon, and the succ which has attended its adoption by many municipal authorit earnestly urges those metropolitan borough councils where this meth is not yet employed to introduce it at the earliest possible moment

The Union is also issuing a leaflet containing informati upon (1) "The Nature of Consumption," (2) "What Lo Authorities can Do to Deal with this Scourge," (3) "The A vantages of the System," and (4) "Where Voluntary Not cation is Adopted." The leaflet contains sound informati written in a plain and simple manner, so that everyo should be able to understand it. We commend the Lo Reform Union for its efforts in the cause of the prev proposed for the destruction of mosquitoes. Many of these preparations are inert, he thinks, and some merely put the insects to sleep for a few hours; but Zanzolina's powder he believes to be a genuine insecticide Burnt at the rate of half a gramme per cubic metre of space this compound proved most effective in completely freeing rooms from mosquitoes of every kind

## VISITING SMALL-POX PATIENTS.

AT a meeting of the Metropolitan Asylums Board on Jan 25th the Hospitals Committee reported that they had considered a letter from the Local Government Board asking for the observations of the managers upon a letter which they had received from Dr. F. J. Allan, medical officer of health of the City of Westminster, as to the vaccination of visitors to patients suffering from small-pox. The committee stated that although every visitor to a patient was strongly pressed to be vaccinated they did not think it possible for the managers to make vaccination a condition of being allowed to enter the hospital. They had now, however, taken the precaution of forwarding the names and addresses of all visitors, whether they accepted vaccination or not, to the medical officer of health in the district in which they resided. They recommended that a reply should be sent to the Local Government Board on the lines of the committee's report. Colonel R Bullock moved as an amendment that vaccination should be made a condition of visitors being allowed to enter small-pox hospitals The amendment having been seconded, the chairman of the Hospitals Committee pointed out that such a practice would never be tolerated in this country. The committee, he considered, had dealt with the question in a most humane manner. The amendment was rejected and the recommendation was adopted

## BLINDNESS ASSOCIATED WITH DEFECTIVE DEVELOPMENT OF THE BACK OF THE SKULL.

BLINDNESS due to defective development or absence of the occipital lobe of the brain is a rare and interesting phenomenon. The most striking anatomical appearance in this case is a characteristic formation of the back of the head marked by absence of the occipital development. In the *American Journal of the Medical Sciences* for January Dr. Charles Oliver reports the case of a girl, four years of age, who was born at full term with a "badly-shaped head and large, prominent eyes. She could see a little till she was three years of age, when she became totally blind and the protrusion of the eyeballs grew more pronounced." The mental condition of the child was good and she was free from epilepsy. Clinical examination showed that the head was disproportionately small and quite deficient posteriorly. The eyes were prominent, divergent, and in constant motion (rotatory nystagmus). The occipital protuberance was almost wanting and the cranial vault presented other interesting features. Thus the superciliary ridges were quite flattened and the forehead was elevated and dome-shaped in the pre-Rolandic region. The lower jaw was incompletely developed and showed a marked recession of the chin. Both ears showed faults of development. The eyelids were large and lax and the pupils were somewhat unequal but capable of reacting well both to light and accommodation. Ocular movements were free in all directions. The ocular media were clear and the fundus was normal on both sides. Repeated tests showed that the patient could not see even the brightest objects and was, in fact, totally blind. Adenoids were present in the nose and throat. The child died in her fourth year from intercurrent disease, but no necropsy could be obtained. Dr. Oliver points out that the posterior part of the skull was quite undeveloped, the bones extending in a plane upwards and forwards (from the cerebellar region) to meet the frontal protuberance which constituted the crown of the head Skulls of this type were rare, but examination of the few known skulls of this form showed that the orbits were shallow and that the anterior coronal region was elevated. The most marked ocular symptoms in such cases were loss of sight, which was total, or almost total, in both eyes, and some degree of exophthalmos. Ocular movements were retained, thus indicating that the ocular motor nerves and nuclei were unaffected. The lesion was one affecting the occipital lobes of the brain either as a defect of development or as the result of damage sustained in early infancy, and the prognosis was hopeless as regards sight. A condition of increased intracranial pressure has been suggested by Friedenwald as being present in such cases and as being one of the causes of the exophthalmos observed, but the causation of such increased pressure is still obscure

## THE RUSSIAN LABOUR LAWS.

A VERY instructive report concerning the Russian labour laws has recently been published by order of M. de Witte, the Imperial Russian Minister of Finance The report was drawn up by M E Dementief, and although it consists of no more than 20 pages the information is so condensed that it is impossible to give a digest of all the facts which it contains. It may be useful, however, to call attention to some of the matters which are dealt with in order to show that the book of which it forms part[1] deserves to be studied by all those who are interested in the labour laws. A point which has received much attention in Russia is the working of the insurance offices which have been started in view of the responsibility that had recently been thrown on employers to give compensation to their workmen or to their relatives in cases in which injuries have resulted either in temporary or permanent disablement or in loss of life. Having regard to the effects of the Workmen's Compensation Acts which have lately been passed in this country there is more than one point mentioned in the Russian report which will be found of interest. For example, the great value of the system of mutual insurance as opposed to that of the system previously in general use is clearly shown. It is also worthy of note that under the Russian system compensation is not given if an accident occurs through malicious design on the part of the sufferer, or in consequence of his being intoxicated or of his being mixed up in a brawl In regard to the control of unhealthy trades little has hitherto been effected. The only industry, indeed, which has been practically controlled is that of the manufacture of phosphorus matches, and this has been done indirectly by means of differential taxation. By this means it has resulted that safety matches are rapidly succeeding the old type of matches which were formerly in very general use. In Russia, as compared with this country, a striking difference exists as to the number of holidays obtained by the workmen Thus, in Russia a contract between an employer and his workmen must definitely contain the provision that all Sundays and 17 "great holidays," or days substituted for them, are to be free from work. Special contracts may, however, be made on occasion, but each special contract provides for only a single day. The wages paid to workmen appear, on the whole, to be low, but in many parts of the country the dwelling houses of the workpeople are provided by the manufacturers. In some districts over half the employés are housed by the manufacturers This fact is not without interest in view of the difficulties presented in England in this matter and the action recently taken by a large firm of glass manufacturers

---

[1] Russia, Its Industries and Trade. Glasgow: Hay, Nisbet and Co 1901.

Pyridine is a poisonous base not so easily soluble in water as in alcohol. Pyridine bases can be easily traced in the mouth of an immoderate smoker, and especially the smoker of cigars. An alcoholic drink is therefore calculated quickly to wash out this poisonous oil and to carry it into the stomach, absorption of the poison ensuing, giving rise to definite toxic symptoms, due not so much to alcohol or pyridine bases alone as to the combined action of both in the manner indicated. Such symptoms would probably be avoided if smokers would abstain from drinking alcohol at the same time that smoking is being indulged in. Many a headache or malaise would thus be guarded against if at the time of smoking no alcoholic beverage were taken. An alternative plan would be to pass all the smoke through an absorbent, such as water, as in the hookah, and thus to exclude the poisonous oils. In such a case the accompaniment of an alcoholic drink would doubtless be much less injurious.

## THE FACULTY OF MEDICINE OF THE UNIVERSITY OF LONDON.

A MEETING of the Faculty of Medicine was held at the University Buildings on Jan. 24th, Mr. H. T. Butlin, the Dean of the Faculty, being in the chair. A communication was received from the Senate stating that in accordance with a recommendation recently presented by the Faculty a considerable increase has been made in the membership of the Faculty. The recommendation presented by the Faculty was as follows:—

> That the Senate should admit to the Faculty of Medicine in accordance with its powers defined in Statute 60 (iii.)—
>
> (1) Every person recognised as a teacher of one of the subjects of "Advanced Medical Studies,"
>
> (2) Every person recognised, or provisionally recognised, as a teacher of one of the subjects of "Intermediate Medical Studies," and
>
> (3) At least one recognised, or provisionally recognised, teacher in each subject of "Preliminary Medical Studies" from each school of the University in the Faculty of Medicine.

The Dean informed the meeting that the Senate had carried out the proposals made by the Faculty and that in consequence the membership had been increased from 158 to 359. He pointed out that the additional members consisted for the most part of the junior teachers on the staffs of the medical schools, upon whose efforts the future prosperity of the Medical Faculty of the University largely depended. At the same time adequate representation upon the Faculty was given to the teachers of anatomy and physiology and of the preliminary sciences. A report from a special committee appointed to consider the subject of the matriculation examination was received and adopted. In it the Faculty reaffirmed a resolution previously passed—

> That no scheme of matriculation will be satisfactory which does not permit a wide choice of subjects for examination so as to meet the requirements of candidates, whether from the "classical" or "modern" side of secondary schools—

and expressed its approval of the proposals made to the Senate by the University's Advisory Board for the admission of students. Dr Lauriston E. Shaw was reappointed honorary secretary to the Faculty.

THERE will be a general meeting of the Medical Officers of Schools Association on Thursday, Feb. 6th, at 4 P.M., at 11, Chandos-street, Cavendish-square, London, W., when Mr. W. N. Shaw, F R.S, late lecturer on physics in the University of Cambridge, will open a discussion on "The Ventilation of School Buildings," with special reference to its application to existing buildings. Other authorities on the subject are expected to speak and some special appliances connected with ventilation will be exhibited

A MEETING of the Sanitary Institute will be held at the Parkes Museum on Wednesday, Feb. 12th, at 8 P.M., when a discussion on the Prevention of Small-pox in the Metropolis will be opened by Mr. A. Wynter Blyth, medical officer of health of St. Marylebone. The chair will be taken by Sir James Crichton-Browne, and as the seating accommodation is limited admission will be by ticket only. Those proposing to attend should apply for tickets of admission to Mr. White Wallis, secretary.

THE Committee of the Charing-cross Hospital Festival Dinner which is to be held on March 19th has secured the support, amongst others, of the Archbishop of Canterbury, the Bishop of London, Earl Roberts, Lord Iveagh, and the Hon. W. F. D. Smith, M.P. Lady Wantage has given £1000 to the hospital fund in memory of the late Lord Wantage.

AT the first meeting of the new Board of Management of the National Hospital for the Paralysed and Epileptic, held on Tuesday, Jan. 28th, the Earl of Harrowby was elected treasurer of the hospital, the Rev. Prebendary Wace chairman, and Mr. J. Danvers Power vice-chairman. Sir Edward Fry and the members of his committee of inquiry were elected honorary life governors of the hospital.

OWING to the closure of half of the hospital for repairs and the necessary conversion of the entertainment hall into a ward for patients it is impossible to hold any lectures at Brompton Hospital for Consumption until after Easter. The list of lectures will be advertised in due course.

THE death of Dr. Edmund Gwynn, late medical officer of health of Hampstead, is announced. Dr. Gwynn graduated as M.D. of St. Andrews in 1862. He was the author of "Shakespeare and Sanitation" and of "The Jerry Builder in Relation to the Dwellings of the Poor."

THE annual meeting of the Neurological Society of London will be held at 11, Chandos-street, W., at 8.30 P.M., on Thursday, Feb. 6th. The President, Mr. H. W. Page, will deliver the annual address on Concussion of the Brain in some of its Surgical Aspects.

THE annual dinner of the West London Medico-Chirurgical Society will be held at Frascati's Restaurant on Wednesday, Feb. 19th, at 7 P.M. Intending diners should communicate with Dr. L. C. T. Dobson, honorary secretary, 59, Addison-gardens, W.

DR. JOHN SHIELDS FAIRBAIRN has been appointed assistant obstetric physician to St. Thomas's Hospital.

## Pharmacological Notes.

### IODINE LEAF OR PAPER PLASTER.

AN ingenious method for the local application of iodine as a counter-irritant has been devised by L. Tixier,[1] consisting of two sheets of filter-paper, one saturated with a solution of potassium iodide and potassium iodate, and the other with potassium acid sulphate. When these are moistened and applied to the skin a considerable amount of iodine is liberated; after placing the moistened sheet on the affected part it is covered with oiled silk or bound with a bandage. The application for 15 minutes has the same effect as a mustard leaf; applied for 25 minutes the result is equal to two or three paintings with tincture of iodine; for from 25 to 45 minutes, the effect is that of strong iodised wool; in one hour the action is vesicant. The slight pain occasioned by the application disappears in 10 minutes after the removal of the papers. Directions are given for the preparation of the papers. When dry an iodide paper is separated from an acid of tuberculosis and may inform our readers that copies of the leaflet for distribution can be obtained from the secretary of the Union, Trafalgar-buildings, Charing-cross, W.C. We may remark in addition that the London Reform Union could do another excellent work by pointing out how to avoid, or at all events to minimise, the effects of small-pox, a disease at present very prevalent in the metropolis. If the London Reform Union would issue a simple leaflet dealing with this disease and with the figures recently published by the Metropolitan Asylums Board as to the incidence of small-pox in vaccinated and in non-vaccinated persons respectively it would go far to do away with the honest if altogether foolish prejudice which exists against vaccination in so many quarters.

---

## THE FELLOWS' DINNER OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE annual Fellows' dinner of the Royal Medical and Chirurgical Society will be held at the Whitehall Rooms of the Hôtel Métropole on Wednesday evening, Feb 26th, at 7.30. It used to be said that the premier medical society was inhospitable, but since the excellent precedent of inviting guests to the annual dinner was created by Mr. Timothy Holmes, when he filled the chair, the interesting series of Fellows' dinners has removed any ground, if it ever existed, for such a reproach. At the next dinner the chair will be taken by the President, Dr. F W Pavy, M.D, LL.D., F.R.S., and among the guests are included the President of the Royal College of Physicians of London (Sir William S. Church), the President of the General Medical Council (Sir William Turner), the Director-General of the Royal Navy Medical Service (Sir Henry Norbury), the Director-General of the Army Medical Service (Surgeon-General Taylor), the Principal of the University of London (Professor Rucker), the Secretary of the Royal Society (Sir Michael Foster, M.P.), Mr. Ouless, R.A., and Dr. Conan Doyle.

## THE PROPOSED UNIVERSITY FOR LIVERPOOL.

THE public meeting of the citizens of Liverpool held at the Liverpool Town-hall on Jan. 27th to consider the desirability of establishing a separate university for that city was a pronounced success. The meeting was presided over by the Lord Mayor of Liverpool (Mr A. O. Petrie) and was attended by a thoroughly representative and influential gathering, which included the Earl of Derby, K.G., the Lord Bishop of Liverpool (Dr Chavasse), Sir John Brunner, Bart., M.P., Sir William H Tate, Bart., Sir William Mitchell Banks, Sir William Forwood, the principal of University College, Liverpool (Mr. A. W. W. Dale), Archdeacon Madden, the Rev Dr Watson (Ian MacLaren), and others The Lord Mayor announced that £80,000 had already been subscribed towards the realisation of the project, and pointed out that, although differences of opinion existed in Liverpool on many subjects in connexion with the "omnibus" Bill of the Liverpool Corporation about to be promoted in Parliament, not a single vote had been recorded against that part of it which asked for power to assist the proposed university. The motion relating to the establishment of a university for Liverpool was proposed by the Earl of Derby, who said that they wanted to bring university facilities within the reach of all they possibly could. Dr. Chavasse seconded the motion in an eloquent speech and said that University College, Liverpool, with its 26 professors and some 60 readers, had surely a claim to be recognised as a university which would be a coping-stone of the educational system for which Liverpool was famous It would help on merchants, engineers, and men of science to compete with those of the continent. The motion was supported by Principal Dale, Sir William Mitchell Banks, and others, and was carried. The keystone of all the speeches was progress; there was no thought of rivalry with the old universities.

## THE NEW WARRANT FOR THE ARMY MEDICAL SERVICE.

MR. BRODRICK has announced in Parliament that the speedy appearance of the new warrant for the Army Medical Service may be expected. We hope and indeed believe that when it appears it will be found that due consideration has been given to the objections urged against the original scheme by the subcommittee of the British Medical Association and by ourselves.

## THE NOTIFICATION OF CHICKEN-POX.

THE London County Council have issued an order pursuant to a resolution of the Council passed on Jan. 28th The order was advertised on Jan. 30th and comes into force at the expiration of one week from that date. Our readers will remember that in our issue of Jan. 25th we noted that eight metropolitan boroughs had already declared chicken-pox to be a notifiable disease. The London County Council order runs as follows :—

> The London County Council do hereby resolve and order that Section 55 of the Public Health (London) Act, 1891, with respect to the notification of infectious disease shall apply in the administrative county of London, for a period of three calendar months, to the disease known as chicken pox, and the Council do hereby declare that the case is one of emergency owing to the prevalence of small pox in London, and the fact that the failure in many cases to distinguish between chicken pox and small pox has led, and is leading, to the spread of the latter disease.

## THE SANITARY INSTITUTE LECTURES.

THE thirty-third course of Lectures and Demonstrations for Sanitary Officers will be delivered during the months of February, March, and April, 1902, at the Parkes Museum, Margaret-street, London, W. The lectures, which will be given at 7 P.M., are divided into two courses, the first dealing with Elementary Physics and Chemistry in relation to Water, Soil, Air, Ventilation, and Meteorology, Public Health Statutes, By-laws, Municipal Hygiene, &c, together with practical demonstrations of measurements and drawing plans to scale The second course embraces lectures on Meat and Food Inspection and the taking of Samples of Water, Food, and Drugs for Analysis. Arrangements have also been made for the inspection of disinfecting stations, soap-works, common lodging-houses, sewage-farms, waterworks, dairy farms, and such like places, practical demonstrations being given at the same time where necessary. Among the lecturers are Dr. E J. Steegmann, Dr. J. Priestley, Mr. A. W. Harris, Dr. E Petronell Manby, and Dr. H. R. Kenwood. The fee for Part I. (25 lectures) is £2 12*s.* 6*d.*, and for Part II. (seven lectures) £1 1*s* The fee for the complete course is £3 3*s*

## THE POISONOUS COÖPERATION OF ALCOHOL AND TOBACCO.

IT cannot be doubted that when evil effects ensue upon smoking tobacco they are very much intensified by indulgence in alcohol Further, though even after a more than moderate indulgence in tobacco no toxic symptoms such as headache and stupor may supervene yet such would probably be the case if alcoholic drinking was practised at the same time. The powerfully solvent action of alcohol is sufficient explanation of this. It is, of course, well known in pharmacology that the active constituents of drugs are, as a rule, readily soluble in alcohol though not in water, and hence the class of preparations known as tinctures. Similarly nicotine and the pyridine bases are very easily soluble in alcohol. The chief poisonous constituent of tobacco smoke is pyridine and not nicotine important to note that the number of single-room tenements containing more than two occupants declined from 57,000 to 41,000, while the number of one-roomed tenements with six or more occupants declined from 4000 to 1800. The tenements of two rooms showed a slight, and those of three and four rooms a marked, increase upon the numbers returned at the previous census.

The proportion of single-room tenements (which averaged 15 per cent. in all London) showed wide variations in the several boroughs, ranging from 3·5 per cent. in Lewisham, 4·1 in Wandsworth, and 6·4 in Hampstead, to 24·8 per cent. in Shoreditch, 26·3 in St. Marylebone, 26·4 in Finsbury, and 27·0 in Holborn. In the borough of Stepney, consisting of the Whitechapel, St. George's-in-the-East, Stepney, and Mile End Old Town registration districts, which during the last intercensal period received a large number of foreign immigrants, the proportion of one-room tenements did not exceed 21·7 per cent, showing a marked reduction from the proportion in 1891.

The occupational statistics now published are very complete, and as they are separately given for each of the metropolitan boroughs, as well as for the county as a whole, they will be appreciated by those who have at heart the welfare of the poorer classes in these areas respectively. In the county of London there were "engaged in occupation" 1,400,000 males and 719,000 females over ten years of age. Of "unoccupied" persons above the age of 10 years there were enumerated 274,000 males and 1,205,000 females. At the census of 1891 the proportion of the population engaged in occupation was 82·8 per cent. in the case of males, and 38·4 in the case of females. At the recent census the percentages were 83·6 and 37·4 respectively. Among occupations employing large numbers of persons commercial clerks have increased by 181 per cent. and therefore more rapidly than any others. Sick nurses, domestic indoor servants, and printers come next, with rates of increase ranging from 74 to 78 per cent On the other hand, there has been a slight falling off in the number of seamstresses and of boot, shoe, &c. makers, and a great falling off in that of artificial flower makers amounting to 42 per cent.

As a means of estimating the degree of prosperity enjoyed by the several classes of the community the proportion of domestic servants employed is usually considered a safe guide. Taking the metropolis as a whole the proportion of domestic servants of both sexes is rather less than one servant to four houses The proportion to 100 separate houses varies in the metropolitan boroughs from 5·7 in Shoreditch and in Bethnal Green to 65·8 in Westminster, 80·0 in Kensington, and 81·4 in Hampstead.

A very full description is given in the report of the occupations followed by foreigners now resident in London who at the date of the census numbered more than 135,000. Of these, not fewer than 54,000 in round numbers, or 40 per cent., were enumerated in the borough of Stepney, of the population of which borough foreigners constitute more than 18 per cent

The number of persons in London who were returned as blind was 3556, almost identical with the number so returned at the previous census. Deaf and dumb persons numbered 2057, or 71 less than in the year 1891. Lunatics now number 3562, and imbecile or feeble-minded, 3496. The total of these is now 7058, against 5771 at the previous census. Of the 3556 blind persons 140 were below 10 years of age, and 2558 were retired or unoccupied, leaving about 858, or about one-quarter of the whole, engaged in work. Of these, 673 were males and the rest were females. Of the latter, 110 were unmarried and 75 were married or widowed. Those described as blind from childhood include 88 "occupied" males and 42 "occupied" females.

## PROFESSIONAL UNION.

FROM time to time particulars of a dispute between the Teversal Colliery Club and their surgeon have been published. In view of recent developments we give the following brief *résumé* of the matter which has been furnished to us by the honorary secretary of the Midland Medical Union.

In 1901 Dr. W. C. Rainsbury of Skegby, who held a colliery appointment to the Teversal Colliery Club, commenced to charge the fee of 21*s.* for midwifery cases. This was an increase from 10*s.* 6*d.* In consequence Dr. Rainsbury was threatened with dismissal from his appointment. A deputation from the Midland Medical Union waited upon the club committee to point out the reasonableness of the fee and to ask them to give the matter their careful consideration. However, they sent Dr. Rainsbury an agreement to sign in which he should bind himself to charge a sum of 10*s.* 6*d.* for members' wives attended by him in their confinements. This he refused to do, and in consequence was served with three months' notice. The colliery club then advertised for a surgeon; the Union advertised warning men not to accept the post, and advertisements from the colliery club were not inserted in the medical journals. The club, however, managed to secure a medical man who agreed to accept the appointment; but from knowledge which came to the club committee a letter was sent to him asking him to come at once and inclosing him three months' notice; in consequence of this he never came to take up his appointment. The result was that after Dr. Rainsbury's notice expired on June 25th, 1901, the club was without a medical officer, and Dr. Rainsbury continued to attend the men and their families, but at private rates.

In November, 1901, the club secured the services of Dr. Alexander David Crawford who took Dr. Rainsbury's appointment on condition that he should also be given the appointment of a neighbouring practitioner under the same club committee—a practitioner who had been asked to accept Dr. Rainsbury's post and had refused. This practitioner (Dr. E. Mitchell of Sutton-in-Ashfield) was forthwith dismissed by the committee and Dr. Crawford introduced a partner—Mr. Robert James Farman—into Sutton-in-Ashfield to carry on that part of the work.

This step on the part of Dr. Crawford and his partner was taken after the case had been fully explained to them, and after the Midland Medical Union, acting on behalf of the local medical men, had begged Dr. Crawford to have nothing to do with the appointment. These two medical men are now carrying on the work for these collieries.

The Midland Medical Union wish to place this statement of facts before the profession generally and ask for expressions of opinion with regard to the action of Dr. Crawford and Mr. Farman.

The council of the Midland Medical Union at a meeting held in Nottingham on Jan. 17th, 1902, declared Dr. Crawford and Mr. Farman to be opposed to the objects and interests of the Union and by a previous resolution of this Union every member is pledged to abstain from giving such practitioners any professional assistance by consultation or otherwise.

## Looking Back.

FROM

### THE LANCET, *SUNDAY, FEB.* 1, 1824.

*The case of* C. A. DEMPSTER, *who swallowed a case-knife.*

This unfortunate man died at Middlewick on Friday the 14th, ult. The public will recollect that in attempting some juggling tricks at Carlisle, he swallowed a table knife rather more than nine inches long, which remained in his stomach without exciting any very acute pain, or producing any serious consequence until within a few days of his death. He left Carlisle, with the intention of proceeding to London, where his mother resides, for the purpose of consulting SIR ASTLEY COOPER. During the journey to Manchester he suffered much pain from the jolting of the coach; when finding himself unable to bear the motion of the carriage, he embarked in a canal boat, but being taken very ill in the boat, he was prevented from pursuing his journey further than Middlewick. This case having excited considerable interest in the public mind as also in that of the profession, it may be proper to observe that the body was opened the day after his death, and the knife found in the stomach, which with the other viscera was in a state of inflammation and gangrene. The handle of the knife (which was of bone) was dissolved, as likewise a considerable portion of the blade; so powerful indeed had the knife been acted upon by the juices of the stomach, as to impress very forcibly on the minds of the medical men who opened the body, a belief that had the man continued at paper by a sheet of plain filter paper and the three sheets are fastened together with a composition consisting of paraffin oil, prepared chalk, resin, and oil of turpentine. They are then wrapped in gutta percha tissue to keep them from moisture.

### NATURAL AND ARTIFICIAL PERFUMES.

In an article on Natural and Artificial Perfumes a writer in *Nature*[2] brings forward many points of pharmacological interest. Thus, the oil of bitter almonds, highly esteemed as a flavouring agent and in perfumery, has sometimes been replaced by benzaldehyde, the highly poisonous so called oil of mirbane, which has a similar odour. This substance is prepared from benzyl chloride, small quantities of which are retained by the benzaldehyde with great tenacity and impart to it a penetrating and unpleasant odour. To take another example, oil of turpentine consists essentially of a hydrocarbon of similar molecular type to irone and ionone, the synthetic substances which form the artificial violet perfumes. It is a noteworthy fact that turpentine when administered internally imparts a strong odour of violets to the urine. Little has yet been accomplished towards ascertaining the relation between the odour and the chemical constitution of substances in general. Hydrocarbons as a class possess considerable similarity in odour, so also do the organic sulphides and, to a smaller extent, the ketones. The subject waits for some investigator to correlate the physiological, psychological, and physical aspects of the subject in the same way that Helmholtz did in the science of sound. It seems, as yet, impossible to assign any probable reason for the fact that many substances have a pleasant odour. It may, however, be worth suggesting that certain compounds, such as the volatile sulphides and the indols, have markedly unpleasant odours because they are normal constituents of mammalian excreta and of putrified animal products; the repulsive odours may be simply necessary results of evolutionary processes.

### TEST FOR INDICAN IN URINE.

A. Klett[3] recommends the following test for indican in urine. 10 cubic centimetres of urine are mixed with five cubic centimetres of 25 per cent. hydrochloric acid and a few drops of ammonium persulphate solution. An excess does not matter. If chloroform, on being added, is coloured blue the presence of indican is detected. The ammonium persulphate yields a precipitate with albumen, and the presence of bile pigments produces a green ring where the liquids meet.

## THE LONDON CENSUS OF 1901.

THE first instalment of the detailed abstracts of returns for the census of 1901 has just been issued as a blue-book. It relates to the county of London and occupies 175 pages of closely printed matter.

From the preface we learn that a departure has on this occasion been made from the plan of publication adopted at previous censuses. In 1891 certain groups of facts, such as area, population boundaries, &c., for each of the English counties were collected and issued in one volume, and in subsequent volumes certain other groups of facts relating to the ages, occupation, infirmities, &c., of the people were similarly dealt with.

On the present occasion however, all the statistical data relating to each separate county will be published together, the object apparently being to secure that persons desirous of obtaining information respecting any particular area may find it under the same cover instead of having to search through several volumes for the different series of facts required. Opinions will probably differ as to the wisdom of this change. It is but natural that those who are specially interested in the statistical details of certain localities should feel aggrieved if the turn of their particular county does not come until late in the order of publication, although this order may have been determined, as we believe it has been, strictly on a population basis. There will, however, be no dispute as to the superior claims of the metropolis to priority of publication and the authorities of less important counties may fairly be reminded that in the preliminary report already issued the main facts of area, population, &c., for all the principal divisions and sub divisions of England and Wales have been given in full.

The first thing which attracts attention in the volume before us is a coloured chart of London on a large scale which very clearly shows the several registration, municipal, and Parliamentary areas of the county. As a specimen of modern cartography we scarcely think it equal to similar productions that find their way into this country from France and other parts of the continent. Nevertheless, for the purposes which it is intended to serve it is perhaps sufficient, and it will certainly be appreciated by medical officers of health and the authorities whom they serve as a useful key to the complex and, for different purposes, overlapping areas into which the metropolis is still sub divided, notwithstanding the simplification of areas which is said to have been effected by recent legislation.

The "London" of to day—in which the administrative and registration counties have at last been made co terminous—contains an area of 74,839 statute acres, according to the revised returns of the ordnance survey, and has a population of 4,536,541. In the year 1801 the population of London did not exceed 959,310; it has therefore increased in the course of the last century nearly five fold. The population of the county of London, however, is not now increasing at the rapid rate which prevailed during the earlier decades of the century. Between 1841 and 1851 the rate of increase was 21 per cent., whereas during the last intercensal period the rate was only one third of that amount. The rate of growth of population within the metropolitan area still continues to diminish. This is proved by the fact that from 1891 to 1896 (the year of the quinquennial census) the population had grown at the rate of 4·8 per cent., whereas from the latter year to 1900 the percentage rate of growth did not exceed 2·4.

In the City of London and in six of the central metropolitan boroughs the population has been actually declining, and that very rapidly, for the last 40 years, dwelling-houses having been demolished in large numbers in order to make room for the extension of warehouses and other business premises. Within the decade just closed the population of this area has diminished by 70,000. In "Greater London" however—i.e., the area included within the City and metropolitan police districts—the population has increased during the last 10 years by little short of 1,000,000, the exact rate of increase having been 17 per cent. It is into the outer zone of this area that the displaced population of central London has migrated and thereby caused a local accession to the total in recent years which must be enormous, but which cannot be measured even approximately until the census returns for the counties of Surrey, Kent, Essex, and Hertford are available for analysis.

Passing over, as of little interest to our profession, those sections of the report which deal with Parliamentary, ecclesiastical, and judicial matters, we come to a consideration of those details which relate to the public health and to the sanitary administration of the metropolis. For example, we are especially interested in what the census has to tell us concerning the ages, the housing, and the occupational condition of the labouring classes, concerning their overcrowding on area as well as in rooms, and also concerning the destitution and the infirmities which exist in the several parts of the metropolitan area. At the time of the recent census the county of London was divided into 30 registration districts which are mostly co extensive with Poor-law unions; in 14 out of the 30 cases the areas of the registration districts correspond with those of the newly constituted metropolitan boroughs, so that in these cases the means still exist of comparing the vital statistics of the new areas with those of the old London vestries. Medical officers of health will be glad to note that the present report contains full particulars for each of the metropolitan boroughs concerning the number of tenements occupied by each family and also concerning the occupational condition and the distribution by age and sex of the population. In London as a whole the total number of separate tenements has increased since the previous census by 8·7 per cent. But whilst the tenements containing more than five rooms have increased by 13 per cent., the increase of those with less than five rooms has been only 6·6 per cent. The reduction in the smaller class of tenements was most marked in the tenements of a single room only, which declined from 18 per cent. of the total in the year 1891 to 15 per cent. in 1901. It is further made the fundamental discovery upon which serum diagnosis rests, and that Dr. Grünbaum performed the first actual agglutination by means of human typhoid serum in March, 1896. That he really did so has been certified to by the best authorities—namely, by Gruber and by Nothnagel and Maunaberg.[1] Lastly, it is equally evident that Professor Widal did not publish his first results until some months after Dr. Grünbaum's success had been obtained and published by Professor Gruber.

---

[2] Nature, vol. lxiii., p. 212.

[3] Schweizerische Wochenschrift für Chemie und Pharmacie, vol. xxxix., page 31 (from the Chemiker Zeitung).

In the *Annales Pasteur*, 1897, p. 670, Professor Widal, in discussing this question, has endeavoured to maintain that as his first publication appeared before the first publication of Dr. Grünbaum, the priority, therefore, belongs to him (Professor Widal), on the ground that priority in discovery goes with priority in publication. Evidently, however, this claim cannot be admitted, because it is not correct to say that priority in discovery goes with priority in publication, since priority in discovery is open to being established by all the rules of evidence which hold in regard to all matters in which evidence is considered. By the evidence of Gruber, Nothnagel, and Mannaberg, to whom the facts were well known, Dr. Grünbaum's work was done before Professor Widal's first publication, and therefore the profession is bound to consider Dr. Grunbaum as the original discoverer, or at least as a simultaneous one. It is necessary to add here that Professor Widal has absolutely refused to mention the date of his first successful agglutination, and therefore we may assume, in default of any evidence to the contrary, that his first agglutination was made just prior to his first publication—a view which is further suggested by the fact that Professor Widal evidently published his experiences as soon as they were made (his first paper was based on only six cases). Moreover, it is evident that Professor Widal may have quite easily obtained a hint, sufficing for the basis of the whole of his work, from Professor Gruber's statement at the Wiesbaden Conference. Professor Widal also maintains that Professor Gruber referred on that occasion only to agglutination with serum taken after convalescence and that he himself was the first to work with serum taken during the course of the disease. But Dr. Grünbaum's second and third experiments were made on the eleventh and the seventeenth days of the disease—that is, during its course; and it is evident that Professor Gruber's brief remark might be justifiably held to include this self-evident extension of the general principle. In my opinion Professor Widal's objections do not even touch the main contention in favour of Dr. Grünbaum—namely, that Dr. Grünbaum's first serum diagnoses were certainly carried out months before Professor Widal's first publication. The priority, therefore, rests with Dr. Grünbaum, or at the best Professor Widal can claim only to share the credit with him. Moreover, the work both of Dr. Grünbaum and Professor Widal was based on the fundamental researches of Professor Gruber and Dr. Durham. It is unjust, therefore, to talk of "Widal's test" as if he had made the entire discovery.

I venture to call attention to the matter once more because I see that this injustice continues to be committed in spite of all protests against it As a rule, the victims of such mistakes have little or no means of redress. If they stand up for themselves they are accused of egotism or pretension; if not, they are forgotten. But the matter is not merely a personal one; the fact that the credit for years of important and honest work can be lost in a moment in this manner scarcely tends to encourage the cause of scientific research. It is not possible to conceive that we should be grateful for pathological discoveries, but we might endeavour to be just in regard to them I am not making any attempt to minimise the valuable work of Professor Widal, but am writing only to call attention to the generous remarks of Professor Gruber and to the claims of those who cannot easily speak for themselves.

I am, Sirs, yours faithfully,

Liverpool, Jan. 23rd, 1902. RONALD ROSS.

## THE SANATORIUM TREATMENT OF CONSUMPTION.

*To the Editors of* THE LANCET.

SIRS,—The letter under the heading of "The Personal Factor in Tuberculosis" in THE LANCET of Dec. 28th, 1901, p. 1843, is far from encouraging to those of us who have been doing what we can to promote the sanatorium treatment of tuberculosis. Strong language has been used, for one finds the following expressions—"a national misfortune," "a world calamity," "absurd pretensions," "'cured' dying on all hands," "Abandon hope all ye that enter here" (viz., sanatoriums), besides others with which I need not burden you or your readers. I quite agree with Mr. J. O. R. Braine-Hartnell of the Cotswold Sanatorium who, with other experienced men, recommends prolonged treatment on the lines of the so-called "open-air treatment."

Our sanatoriums, if they are anything, are schools of hygiene; the principles there laid down are, in as far as they are common to the majority of the inmates, intended to be maintained more or less constantly. It is no wonder that some of those who have received most manifest benefit in a sanatorium should break down after their return to their homes, for, instead of observing the rules under which they have so greatly improved, they virtually abandon fresh air, surplus feeding, &c., and follow the manner of life which predisposed them to their primary attacks.

It seems doubtful whether your correspondent has ever spent a week in a properly conducted sanatorium. Had he done so he would have learned that the patients therein are not exposed to a bacillus-contaminated atmosphere, but that by night and by day the treated are breathing air far purer than that which is to be found in most of the sick rooms of Nottingham. Comparison is drawn between sanatoriums for tuberculosis and infectious diseases hospitals. The arrangements of these two kinds of institutions are totally different for the most part. I only refer to one in sanatoriums: the patients are segregated at night time and during the day they are seldom together unless in the open air. The reverse is the rule in fever and such like hospitals. Would your correspondent wish to do away with our hospitals for diphtheria and scarlet fever and to return to the old days when whole families were laid low with these infectious diseases because the first case was not removed from, it may be, the overcrowded room or house?

No, Sirs, we shall continue our works of sanitation, our isolation hospitals, and our sanatoriums, all on "common-sense" and scientific lines. Some day it may please God that we shall be able thereby to stamp out the most dangerous of our epidemic diseases. Mr. E. D. Marriott goes on to assert that want of cubic space and defective drainage are the causes of consumption. Doubtless both these conditions tend to the predisposition to, and aggravation of, tuberculosis, and patients flock to sanatoriums to escape from such insanitary surroundings. One great value of sanatoriums is that they are teaching the public the great importance of fresh air and other advantageous environment. Our hospitals, barracks, poorhouses, prisons, and other public institutions are still suffering not so much from want of cubic space as from lack of fresh air. Other diseases than those due to the tubercle bacilli would be benefited by the so-called "open-air treatment." It is very seldom necessary that a window in a sick-room or a hospital should be entirely shut. The remedy for low temperatures is not shutting out the fresh air, but the supply of warm air, extra clothing, and in many cases extra food.

Since I have been practising in the Italian Riviera I have grieved to see how apparently curable cases of tuberculosis have, to say the least, failed to improve because the virtues of "sanatorium treatment" have not been appreciated by at least the sufferer and I fear occasionally by the patient's medical adviser. Let the National Association for the Prevention of Tuberculosis pursue its beneficent mission, keeping well in view the opening of the "windows of *earth*," of cottage and palace alike, and thereby will come in "a blessing that there shall not be room enough to receive it."

I am, Sirs, yours faithfuly,

San Remo, Italy, Jan. 15th, 1902. W. SOLTAU ECCLES.

## THE DOSE AND LENGTH OF INCUBATION IN MEASLES AND VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—On Christmas Eve a lady and her two children arrived at a country house for the holiday season. Their hostess seemed to have a heavy influenzal cold, but next morning she was manifestly in measles. The children were sent back to London, the mother remaining to

---

[1] THE LANCET, April 21st, 1900, p. 1169.

Carlisle, and been kept in a quiet state, the whole of the knife might have been dissolved, and the case terminated favourably. The public prints having stated that Sir **ASTLEY COOPER** had recommended an operation for extracting the knife, we deem it but justice to the above mentioned gentlemen to state, that they saw the man only about three hours prior to his death, when inflammation and mortification had already commenced.—*Chester Courant.*

# VITAL STATISTICS.

### VACCINATION AND SMALL-POX.

THE Registrar-General's return for the current week contains a table of the deaths from small-pox which have been registered from the beginning of the present epidemic down to Jan. 11th, 1902. The table shows that out of those children and young persons under 20 years in the population of London who were not protected by vaccination, 100 have recently died from small-pox; whilst only four deaths from that disease have occurred among those of the same ages who were ascertained to have been vaccinated in infancy. There are also five cases in which the evidence was insufficient to warrant a definite statement as to vaccination. If the extreme course be taken of counting these five cases with the vaccinated, the figures will show at least 100 deaths from small-pox among the unvaccinated section of the population under 20 years of age, and at most nine deaths among the vaccinated section at the same ages.

### HEALTH OF ENGLISH TOWNS.

THE number of towns dealt with in the Registrar-General's weekly return has now been increased to 76 by the addition of Bournemouth, which has been recently extended, and, as at present constituted, contained a population exceeding 50,000 at the recent census In these 76 large English towns, the aggregate population of which is estimated to be 14,862,003 persons in the middle of the year, 8394 births and 5048 deaths were registered during the week ending Jan. 25th. The annual rate of mortality, which had been 20·1, 18·2, and 17·7 per 1000 in the three preceding weeks, was again 17·7 last week. In London the death-rate was 17·9 per 1000, while it averaged 17·6 in the 75 other large towns. The lowest death-rates in these towns were 6·2 in Walthamstow, 7·1 in Barrow-in-Furness, 7·5 in East Ham, 10·2 in Bournemouth, 10·3 in Derby, 10·8 in Ipswich, 11·2 in Rotherham, and 11·3 in Burton-upon-Trent; the highest rates were 22·0 in Preston, 23·3 in Aston Manor, 23·6 in Liverpool and in Rhondda, 24·1 in Swansea, 26·2 in Stockton-on-Tees, 27·3 in Merthyr Tydfil, and 30·3 in York. The 5048 deaths in these towns last week included 512 which were referred to the principal zymotic diseases, against 482 and 534 in the two preceding weeks; of these 115 resulted from measles, 112 from whooping-cough, 100 from diphtheria, 64 from scarlet fever, 50 from diarrhœa, 38 from small-pox, and 33 from "fever" (principally enteric) No death from any of these diseases occurred in Bournemouth, Burton-on-Trent, Walsall, or Barrow-in-Furness, in the other towns they caused the lowest death rates in Tottenham, Portsmouth, Derby, Halifax, and Swansea, and the highest rates in Willesden, Handsworth, St Helens, Preston, Middlesbrough, Stockton-on-Tees, Rhondda, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Handsworth, St. Helens, Preston, Rotherham, and Merthyr Tydfil; from scarlet fever in Leyton, St. Helens, and Middlesbrough, from diphtheria in Willesden, Walthamstow, Reading, Northampton, Oldham, Burnley, and West Hartlepool; from whooping cough in Devonport, Leeds, Stockton-on-Tees, and Rhondda; and from "fever" in Bootle, York, and Middlesbrough. 34 fatal cases of small-pox were registered in London, and one each in Willesden, Tottenham, Leyton, and Reading, but not one in any other of the 76 large towns. There were 870 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Jan. 25th, against 754, 873, and 877 at the end of the three preceding weeks; 203 new cases were admitted during the week, against 261, 306, and 213 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2987, 2864, and 2760 at the end of the three preceding weeks, had further declined to 2658 on Saturday last; 299 new cases were admitted during the week, against 313, 250, and 288 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 452, 366, and 307 in the three preceding weeks, rose again last week to 357, but were 144 below the corrected average. The causes of 55, or 1·1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Bradford, Leeds, Newcastle, and 45 other smaller towns; the largest proportions of uncertified deaths were registered in Handsworth, Birmingham, Liverpool, Warrington, Blackburn, Preston, Sheffield, Middlesbrough, Stockton-on-Tees, and South Shields.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·6 and 20·8 per 1000 in the two preceding weeks, declined again to 20·3 per 1000 during the week ending Jan 25th, but exceeded by 2·6 the mean rate during the same period in the 76 large English towns. Among the Scotch towns the death-rates ranged from 11·2 in Leith and 18·2 in Greenock to 21·9 in Perth and 22·1 in Glasgow. The 656 deaths in these towns included 31 which were referred to measles, 20 to diarrhœa, 13 to whooping-cough, five to diphtheria, four to scarlet fever, and three to "fever." In all 76 deaths resulted from these principal zymotic diseases last week, against 56 and 63 in the two preceding weeks. These 76 deaths were equal to an annual rate of 2·4 per 1000, which was 0·6 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 23 in each of the two preceding weeks, increased last week to 31, of which 23 were registered in Glasgow and six in Dundee. The deaths from diarrhœa, which had been 19 and 13 in the two preceding weeks, rose again to 20 last week, and included 13 in Glasgow and four in Edinburgh. The fatal cases of whooping-cough, which had been five and 11 in the two preceding weeks, further rose last week to 13, of which 10 occurred in Glasgow. The deaths from diphtheria, which had been five, four, and six in the three preceding weeks, decreased again to five last week, and included three in Aberdeen The fatal cases of scarlet fever, which had been two and six in the two preceding weeks, declined again last week to four, of which two occurred in Greenock. The three deaths from "fever," showed a slight decline from the number in the preceding week, and were all registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 142 and 176 in the two preceding weeks, declined again last week to 128, and were 17 below the number in the corresponding period of last year. The causes of 15, or more than 2 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·4, 25·0, and 23·4 per 1000 in the three preceding weeks, further declined to 20·9 per 1000 during the week ending Jan. 25th. During the past four weeks the death-rate has averaged 24·7 per 1000, the rates during the same period being 18·8 in London and 19·7 in Edinburgh. The 152 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 18 from the number in the preceding week, and included eight which were referred to the principal zymotic diseases, against nine, 10, and six in the three preceding weeks, of these four resulted from diarrhœa, two from whooping-cough, two from "fever," and one from measles These nine deaths were equal to an annual rate of 1·1 per 1000, the zymotic death-rates during the same period being 1·9 in London and 1·1 in Edinburgh. The fatal cases of diarrhœa, which had been three, one, and two in the three preceding weeks, further rose last week to four The mortality from "fever" also showed a slight increase over that registered in the preceding week. The 152 deaths in Dublin last week included 21 of children under one year of age and 48 of persons aged upwards of 60 years, these numbers were respectively 16 and four below those recorded in the preceding week. Four inquest cases and five deaths from violence were registered; and 42, or nearly a third, of the deaths occurred in public institutions The causes of six, or nearly 4 per cent., of the deaths in Dublin last week were not certified.

made the fundamental discovery upon which serum diagnosis rests, and that Dr. Grünbaum performed the first actual agglutination by means of human typhoid serum in March, 1896. That he really did so has been certified to by the best authorities—namely, by Gruber and by Nothnagel and Mannaberg.[1] Lastly, it is equally evident that Professor Widal did not publish his first results until some months after Dr. Grünbaum's success had been obtained and published by Professor Gruber.

In the *Annales Pasteur*, 1897, p. 670, Professor Widal, in discussing this question, has endeavoured to maintain that as his first publication appeared before the first publication of Dr. Grünbaum, the priority, therefore, belongs to him (Professor Widal), on the ground that priority in discovery goes with priority in publication. Evidently, however, this claim cannot be admitted, because it is not correct to say that priority in discovery goes with priority in publication, since priority in discovery is open to being established by all the rules of evidence which hold in regard to all matters in which evidence is considered. By the evidence of Gruber, Nothnagel, and Mannaberg, to whom the facts were well known, Dr. Grünbaum's work was done before Professor Widal's first publication, and therefore the profession is bound to consider Dr. Grünbaum as the original discoverer, or at least as a simultaneous one. It is necessary to add here that Professor Widal has absolutely refused to mention the date of his first successful agglutination, and therefore we may assume, in default of any evidence to the contrary, that his first agglutination was made just prior to his first publication—a view which is further suggested by the fact that Professor Widal evidently published his experiences as soon as they were made (his first paper was based on only six cases). Moreover, it is evident that Professor Widal may have quite easily obtained a hint, sufficing for the basis of the whole of his work, from Professor Gruber's statement at the Wiesbaden Conference. Professor Widal also maintains that Professor Gruber referred on that occasion only to agglutination with serum taken after convalescence and that he himself was the first to work with serum taken during the course of the disease. But Dr. Grünbaum's second and third experiments were made on the eleventh and the seventeenth days of the disease—that is, during its course; and it is evident that Professor Gruber's brief remark might be justifiably held to include this self-evident extension of the general principle. In my opinion Professor Widal's objections do not even touch the main contention in favour of Dr. Grünbaum—namely, that Dr. Grünbaum's first serum diagnoses were certainly carried out months before Professor Widal's first publication. The priority, therefore, rests with Dr. Grünbaum, or at the best Professor Widal can claim only to share the credit with him. Moreover, the work both of Dr. Grünbaum and Professor Widal was based on the fundamental researches of Professor Gruber and Dr. Durham. It is unjust, therefore, to talk of "Widal's test" as if he had made the entire discovery.

I venture to call attention to the matter once more because I see that this injustice continues to be committed in spite of all protests against it. As a rule, the victims of such mistakes have little or no means of redress. If they stand up for themselves they are accused of egotism or pretension; if not, they are forgotten. But the matter is not merely a personal one; the fact that the credit for years of important and honest work can be lost in a moment in this manner scarcely tends to encourage the cause of scientific research. It is not possible to conceive that we should be grateful for pathological discoveries; but we might endeavour to be just in regard to them. I am not making any attempt to minimise the valuable work of Professor Widal, but am writing only to call attention to the generous remarks of Professor Gruber and to the claims of those who cannot easily speak for themselves.

I am, Sirs, yours faithfully,

Liverpool, Jan. 23rd, 1902. RONALD ROSS.

## THE SANATORIUM TREATMENT OF CONSUMPTION.

*To the Editors of* THE LANCET.

SIRS,—The letter under the heading of "The Personal Factor in Tuberculosis" in THE LANCET of Dec. 28th, 1901, p. 1843, is far from encouraging to those of us who have been doing what we can to promote the sanatorium treatment of tuberculosis. Strong language has been used, for one finds the following expressions—"a national misfortune," "a world calamity," "absurd pretensions," "'cured' dying on all hands," "Abandon hope all ye that enter here" (*viz., sanatoriums*), *besides others with* which I need not burden you or your readers. I quite agree with Mr. J. O. R. Braine-Hartnell of the Cotswold Sanatorium who, with other experienced men, recommends prolonged treatment on the lines of the so-called "open-air treatment."

Our sanatoriums, if they are anything, are schools of *hygiene; the principles there laid down are, in as far as they* are common to the majority of the inmates, intended to be maintained more or less constantly. It is no wonder that some of those who have received most manifest benefit in a sanatorium should break down after their return to their homes, for, instead of observing the rules under which they have so greatly improved, they virtually abandon fresh air, surplus feeding, &c., and follow the manner of life which predisposed them to their primary attacks.

It seems doubtful whether your correspondent has ever spent a week in a properly conducted sanatorium. Had he done so he would have learned that the patients therein are not exposed to a bacillus-contaminated atmosphere, but that by night and by day the treated are breathing air far purer than that which is to be found in most of the sick rooms of Nottingham. Comparison is drawn between sanatoriums for tuberculosis and infectious diseases hospitals. The arrangements of these two kinds of institutions are totally different for the most part. I only refer to one in sanatoriums: the patients are segregated at night time and during the day they are seldom together unless in the open air. The reverse is the rule in fever and such like hospitals. Would your correspondent wish to do away with our hospitals for diphtheria and scarlet fever and to return to the old days when whole families were laid low with these infectious diseases because the first case was not removed from, it may be, the *overcrowded room or house?*

No, Sirs, we shall continue our works of sanitation, our isolation hospitals, and our sanatoriums, all on "common-sense" and scientific lines. Some day it may please God that we shall be able thereby to stamp out the most dangerous of our epidemic diseases. Mr. E. D. Marriott goes on to assert that want of cubic space and defective drainage are the causes of consumption. Doubtless both these conditions tend to the predisposition to, and aggravation of, tuberculosis, and patients flock to sanatoriums to escape from such insanitary *surroundings. One great value of sanatoriums is that they are* teaching the public the great importance of fresh air and other advantageous environment. Our hospitals, barracks, poorhouses, prisons, and other public institutions are still suffering not so much from want of cubic space as from lack of fresh air. Other diseases than those due to the tubercle bacilli would be benefited by the so-called "open-air treatment." It is very seldom necessary that a *window in a sick-room or a hospital* should be entirely shut. The remedy for low temperatures is not shutting out the fresh air, but the supply of warm air, extra clothing, and in many cases extra food.

Since I have been practising in the Italian Riviera I have grieved to see how apparently curable cases of tuberculosis have, to say the least, failed to improve because the virtues of "sanatorium *treatment*" have not been appreciated by at least the sufferer and I fear occasionally by the patient's medical adviser. Let the National Association for the Prevention of Tuberculosis pursue its beneficent mission, keeping well in view the opening of the "windows of *earth*," of cottage and palace alike, and thereby will come in "a blessing that there shall not be room enough to receive it."

# THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Staff Surgeons.—A. G. Wildey to the *Illustrious*, and T. J. Crowley to the *Revenge*. Surgeons.—R. St. G. S. Bond to the *Assaye*; A. J. Laurie to the *Highflyer*, additional; R. M. Richards to the *Jason*; G. G. Borrett to the *Pylades*, additional; J. O'Hea to the *Minerva*; and L. Lindop to the *Camperdown*.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel A. M. Davies is ordered to Portland to investigate the recurrence of enteric fever among the troops there.—Lieutenant H. W. Long is held in readiness for service in India.

### IMPERIAL YEOMANRY.

*Norfolk* (*King's Own*): Surgeon-Captain J. F. Gordon Dill, from Hampshire Imperial Yeomanry, to be Surgeon-Captain.

### VOLUNTEER CORPS.

*Royal Garrison Artillery*: 1st City of London: Surgeon-Captain A. Allport resigns his commission, 1st Worcestershire: George Herbert Rutter to be Surgeon-Lieutenant. *Royal Engineers*: 2nd Cheshire (Railway): Surgeon-Lieutenant-Colonel J. Atkinson retires under paragraph 111 Volunteer Regulations, with permission to retain his rank and to wear the uniform of the corps on retirement. *Rifle*: 1st Roxburgh and Selkirk (the Border): Surgeon-Lieutenant W. Doig to be Surgeon-Captain. 1st (City of Dundee) Volunteer Battalion, the Black Watch (Royal Highlanders): Robert Thornton to be Surgeon-Lieutenant. 7th (Clackmannan and Kinross) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant G. T. Sinclair resigns his commission.

### SOUTH AFRICAN WAR NOTES.

Civil Surgeons Penn and Bensusan were both reported to be seriously ill at Graff Reinet on Jan. 24th.

### SOUTH AFRICAN REWARDS.

Lieutenant John Macfarlane Sloan, R.A.M.C., has been appointed to the Distinguished Service Order for devotion to duty at Bakenlaagte.

### SOUTH AFRICAN AFFAIRS.

WHAT with the increased pace at which the "wearing-down" process has been going on of late among the Boer forces in the field and the general belief that great efforts will be made to bring the war in South Africa to an end before the King's coronation occurs, a more hopeful tone seems to prevail. Mr. Balfour's very guarded announcement in the House of Commons that a communication had been received from the Dutch Government came somewhat as a surprise. This announcement, together with other signs of failing power and resolution on the part of the Boers, has been seized upon as indicating that their cause is tottering to its fall. But in the absence of any Boer Government or of anyone armed with the requisite authority to speak on its behalf it is difficult to see how the British Government is to take any steps, and it would be premature to form any opinion as to whether the Dutch note will be followed by any result. In the meantime there is an increased activity on the part of the various British columns in the field; forced marches with fighting on a small scale are taking place in numerous directions.

Our troops have of late been subjected to great exposure and much fatigue. There has been much heavy rain and there is still a good deal of sickness from enteric fever, dysentery, and diseases incidental to field service under such conditions.

It probably did not escape the attention of our readers that in the debate on the war raised in the House of Lords by the Earl of Wemyss on Jan. 27th the Army Medical Service came in for its share of attention. The strictures of Lord Tweedmouth on the shortcomings of the Government in its conduct of the war led Lord Raglan, in replying to them, to speak among other things in highly favourable terms of the services of the medical department and its officers. What Lord Raglan said is somewhat differently reported in different journals, but all agree in stating that he spoke in eulogistic terms of the work that had been done. As regards the alleged deficiency of the army medical service, it had, he said, been agreed on all sides at the beginning of the war that the effective number of men that should be sent out was about 70,000, and considering that they had subsequently to deal with the wants of 200,000 men the efforts made by the army medical service could hardly under the circumstances have been surpassed. Lord Raglan at the same time added that he fully recognised the services rendered to the army and to the Boers and the natives by the voluntary associations which supplemented the efforts of the army medical staff. It will be seen that all we have contended for is officially admitted by Lord Raglan. The late Director-General was obviously not responsible for the fact that his department was, and for years had been, an undermanned department; but he nevertheless sent out all the necessary medical staff and hospital equipment which he was called upon to provide for the force originally fixed upon by the military authorities and War Office. He had no power to do more than was thought necessary at the time.

It is stated that scarlet fever has broken out on board the training ship *Impregnable* at Devonport. There are some 1250 boys on board and 100 of these have already been sent to the Royal Naval Hospital, Stonehouse.

# Correspondence.

"Audi alteram partem."

## WHO DISCOVERED SERUM DIAGNOSIS?

*To the Editors of* THE LANCET.

SIRS,—I was glad to hear Professor Gruber declare himself at his first Harben Lecture, delivered at King's College on Jan. 13th, on the question of priority in connexion with serum diagnosis. If I remember his words aright he said that he was most surprised to find people in this country giving the credit for the discovery of serum diagnosis to a foreigner when this credit really belongs chiefly to two of our own countrymen—namely, Dr. H. E. Durham and Dr. A. S. Grünbaum. The history of the discovery appears to be as follows. After some preliminary observations by Pfeiffer and Bordet, Gruber and Durham, in 1895, ascertained by extensive and careful experiments the fundamental fact that immune serum can agglutinate the bacteria concerned. This was undoubtedly the fundamental discovery upon which serum diagnosis rests and it now became necessary to apply it to the cases of special diseases. The first application was made by Dr. Grünbaum in March, 1896. Dr. Grünbaum was at the time working in Gruber's laboratory in Vienna. He applied the reaction to several cases of typhoid fever obtained from Nothnagel's clinic and obtained positive and genuine results. The first test was made on March 14th on a case of typhoid fever of 27 days' duration; the second was obtained on March 22nd on a case of typhoid fever of 11 days' duration; and the third on March 23rd on a case of 17 days' duration. All these were positive; and numerous control experiments made at the same time sufficed to establish the utility of serum diagnosis in typhoid fever and also to demonstrate the feasibility of using serum in large dilutions. Unfortunately, no more cases were available in Vienna after the third case just referred to until the following June. Meantime, on April 9th Professor Gruber attended a medical congress at Wiesbaden and announced there that positive agglutination results might be obtained by the serum of convalescent cases of typhoid fever. This announcement was made very briefly and did not mention Dr. Grünbaum's or any other person's name. Owing to the continued paucity of cases and to the wish of Professor Gruber and Dr. Grünbaum not to publish the discovery until more material had been collected no further record was put before the profession. Suddenly, however, Professor F. Widal described before the Société Médicale des Hôpitaux, Paris, some successful agglutinations by serum from typhoid patients. This was followed by a succession of papers by Professor Widal reporting many more successful cases; and the result of these publications was that Professor Widal has obtained throughout the world the credit for having discovered serum diagnosis. Owing to continued paucity of cases of typhoid fever in Vienna and to other unavoidable causes Dr. Grünbaum was not able to publish his first paper until September, 1896.

It is clear from this history, which cannot be disputed, that Professor Gruber and Dr. Durham (and perhaps Bordet) made the fundamental discovery upon which serum diagnosis rests, and that Dr. Grünbaum performed the first actual agglutination by means of human typhoid serum in March, 1896. That he really did so has been certified to by the best authorities—namely, by Gruber and by Nothnagel and Maunaberg.[1] *Lastly, it is equally evident that Professor* Widal did not publish his first results until some months after Dr. Grünbaum's success had been obtained and published by Professor Gruber.

In the *Annales Pasteur*, 1897, p. 670, *Professor Widal, in* discussing this question, has endeavoured to maintain that as his first publication appeared before the first publication of Dr. Grünbaum, the priority, therefore, belongs to him (Professor Widal), on the ground that priority in discovery goes with priority in publication. Evidently, however, this claim cannot be admitted, because it is not correct to say that priority in discovery goes with priority in publication, since priority in discovery is open to being established by all the rules of evidence which hold in regard to all matters in which evidence is considered. By the evidence of Gruber, Nothnagel, and Mannaberg, to whom the facts were well known, Dr. Grunbaum's work was done before Professor Widal's first publication, and therefore the profession is bound to consider Dr. Grünbaum as the original discoverer, or at least as a simultaneous one. It is necessary to add here that Professor Widal has absolutely refused to mention the date of his first successful agglutination, and therefore we may assume, in default of any evidence to the contrary, that his first agglutination was made just prior to his first publication—a view which is further suggested by the fact that Professor Widal evidently published his experiences *as soon as they were made* (his first paper was based on only six cases). Moreover, it is evident that Professor Widal may have quite easily obtained a hint, sufficing for the basis of the whole of his work, from Professor Gruber's statement at the Wiesbaden Conference. Professor Widal also maintains that Professor Gruber referred on that occasion only to agglutination with serum taken after convalescence and that he himself was the first to work with serum taken during the course of the disease. But Dr. Grünbaum's second and third experiments were made on the eleventh and the seventeenth days of the disease—that is, during its course; and it is evident that Professor Gruber's brief remark might be justifiably held to include this *self-evident extension of* the *general principle. In my* opinion Professor Widal's objections do not even touch the main contention in favour of Dr. Grünbaum—namely, that Dr. Grünbaum's first serum diagnoses were certainly carried out months before Professor Widal's first publication. The priority, therefore, rests with Dr. Grünbaum, or at the best *Professor* Widal can claim only to share the credit with him. Moreover, the work both of Dr. Grünbaum and Professor Widal was based on the fundamental researches of Professor Gruber and Dr. Durham. It is unjust, therefore, to talk of "Widal's test" as if he had made the entire discovery.

I venture to call attention to the matter once more because I *see that this injustice* continues to be committed in spite of all protests against it. As a rule, the victims of such mistakes have little or no means of redress. If they stand up for themselves they are accused of egotism or pretension; if not, they are forgotten. But the matter is not merely a personal one; the fact that the credit for years of important and honest work can be lost in a moment in this manner *scarcely tends to encourage* the cause *of scientific research.* It is not possible to conceive that we should be grateful for pathological discoveries; but we might endeavour to be just in regard to them. I am not making any attempt to minimise the valuable work of Professor Widal, but am writing only to call attention to the generous remarks of Professor Gruber and to the claims of those who cannot *easily speak for themselves.*

I am, Sirs, yours faithfully,

Liverpool, Jan. 23rd, 1902. RONALD ROSS.

---

## THE SANATORIUM TREATMENT OF CONSUMPTION.

*To the Editors of* THE LANCET.

SIRS,—The letter under the heading of "The Personal Factor in Tuberculosis" in THE LANCET of Dec. 28th, 1901, p. 1843, is far from encouraging to those of us who have been doing what we can to promote the sanatorium treatment of tuberculosis. Strong language has been used, for one finds the following expressions—"a national misfortune," "a world calamity," "absurd pretensions," "'cured' dying on all hands," "Abandon hope all ye that enter here" (viz., sanatoriums), besides others with which I need not burden you or your readers. I quite agree with Mr. J. O. R. Braine-Hartnell of the Cotswold Sanatorium *who, with other experienced men, recommends prolonged* treatment on the lines of the so-called "open-air treatment."

Our sanatoriums, if they are anything, are schools of hygiene; the principles there laid down are, in as far as they are common to the majority of the inmates, intended to be maintained more or less constantly. It is no wonder that some of those who have received most *manifest* benefit *in a* sanatorium should break down after their return to their homes, *for*, instead of observing the rules under which they have so greatly improved, they virtually abandon fresh air, surplus feeding, &c., and follow the manner of life which predisposed them to their primary attacks.

It seems doubtful whether your correspondent has ever spent a week in a properly conducted sanatorium. *Had he* done so he would have learned that the patients therein are not exposed to a bacillus-contaminated atmosphere, but that by night and by day the treated are breathing air far purer than that which is to be found in most of the sick rooms of Nottingham. Comparison is drawn between sanatoriums for tuberculosis and infectious diseases hospitals. The arrangements of these two kinds of institutions are *totally different for the most part. I only refer to one in sanatoriums:* the patients are segregated at night time and during the day they are seldom together unless in the open air. The reverse is the rule in fever and such like hospitals. Would your correspondent wish to do away with our hospitals for diphtheria and scarlet fever and to return to the old days when whole families were laid low with these infectious diseases because the first case was not removed from, it may be, the overcrowded room or house?

No, Sirs, we shall continue our works of sanitation, our isolation hospitals, and our sanatoriums, all on "common-sense" and scientific lines. Some day it may please God that we shall be able thereby to stamp out the most dangerous of our epidemic diseases. Mr. E. D. Marriott goes on to assert that want of cubic space and defective drainage are the causes of consumption. Doubtless both these conditions tend to the predisposition to, and aggravation of, tuberculosis, and patients flock to sanatoriums to escape from such insanitary surroundings. One great value of sanatoriums is that they are teaching the public the great importance of fresh air and other advantageous environment. *Our hospitals, barracks,* poorhouses, prisons, and other public institutions are still suffering not so much from want of cubic space as from lack of fresh air. Other diseases than those due to the tubercle bacilli would be benefited by the so-called "open-air treatment." It is very seldom necessary that a window in a sick-room or a hospital should be entirely shut. The remedy for low temperatures is not shutting out the fresh air, but the supply of warm air, extra clothing, and in many cases extra food.

Since I have been practising in the Italian Riviera I have grieved to see how apparently curable cases of tuberculosis have, to say the least, failed to improve because the virtues of "sanatorium treatment" have not been appreciated by at least the sufferer and I fear occasionally by the patient's medical adviser Let the National Association for the Prevention of Tuberculosis pursue its beneficent mission, keeping well in view the opening of the "windows of *earth*," of cottage and palace alike, and thereby will come in "a blessing that there shall not be room enough to receive it."

*I am, Sirs, yours faithfuly,*

San Remo, Italy, Jan. 15th, 1902. *W. SOLTAU ECCLES.*

# THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Staff Surgeons. —A. G. Wildey to the *Illustrious*, and T. J. Crowley to the *Revenge*. Surgeons.—R. St. G. S. Bond to the *Assaye;* A. J. Laurie to the *Highflyer*, additional; R. M. Richards to the *Jason;* G. G. Borrett to the *Pylades*, additional; J. O'Hea to the *Minerva;* and L. Lindop to the *Camperdown*.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel A. M. Davies is ordered to Portland to investigate the recurrence of enteric fever among the troops there.—Lieutenant H. W. Long is held in readiness for service in India.

### IMPERIAL YEOMANRY.

*Norfolk* (*King's Own*)*:* Surgeon-Captain J. F. Gordon Dill, from Hampshire Imperial Yeomanry, to be Surgeon-Captain.

### VOLUNTEER CORPS.

*Royal Garrison Artillery:* 1st City of London: Surgeon-Captain A. Allport resigns his commission, 1st Worcestershire: George Herbert Rutter to be Surgeon-Lieutenant. *Royal Engineers:* 2nd Cheshire (Railway): Surgeon-Lieutenant-Colonel J. Atkinson retires under paragraph 111 Volunteer Regulations, with permission to retain his rank and to wear the uniform of the corps on retirement. *Rifle:* 1st Roxburgh and Selkirk (the Border): Surgeon-Lieutenant W. Doig to be Surgeon-Captain. 1st (City of Dundee) Volunteer Battalion, the Black Watch (Royal Highlanders): Robert Thornton to be Surgeon-Lieutenant. 7th (Clackmannan and Kinross) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant G. T. Sinclair resigns his commission.

### SOUTH AFRICAN WAR NOTES.

Civil Surgeons Penn and Bensusan were both reported to be seriously ill at Graff Reinet on Jan. 24th.

### SOUTH AFRICAN REWARDS.

Lieutenant John Macfarlane Sloan, R.A.M.C., has been appointed to the Distinguished Service Order for devotion to duty at Bakenlaagte.

### SOUTH AFRICAN AFFAIRS.

WHAT with the increased pace at which the "wearing-down" process has been going on of late among the Boer forces in the field and the general belief that great efforts will be made to bring the war in South Africa to an end before the King's coronation occurs, a more hopeful tone seems to prevail. Mr. Balfour's very guarded announcement in the House of Commons that a communication had been received from the Dutch Government came somewhat as a surprise. This announcement, together with other signs of failing power and resolution on the part of the Boers, has been seized upon as indicating that their cause is tottering to its fall. But in the absence of any Boer Government or of anyone armed with the requisite authority to speak on its behalf it is difficult to see how the British Government is to take any steps, and it would be premature to form any opinion as to whether the Dutch note will be followed by any result. In the meantime there is an increased activity on the part of the various British columns in the field; forced marches with fighting on a small scale are taking place in numerous directions.

Our troops have of late been subjected to great exposure and much fatigue. There has been much heavy rain and there is still a good deal of sickness from enteric fever, dysentery, and diseases incidental to field service under such conditions.

It probably did not escape the attention of our readers that in the debate on the war raised in the House of Lords by the Earl of Wemyss on Jan. 27th the Army Medical Service came in for its share of attention. The strictures of Lord Tweedmouth on the shortcomings of the Government in its conduct of the war led Lord Raglan, in replying to them, to speak among other things in highly favourable terms of the services of the medical department and its officers. What Lord Raglan said is somewhat differently reported in different journals, but all agree in stating that he spoke in eulogistic terms of the work that had been done. As regards the alleged deficiency of the army medical service, it had, he said, been agreed on all sides at the beginning of the war that the effective number of men that should be sent out was about 70,000, and considering that they had subsequently to deal with the wants of 200,000 men the efforts made by the army medical service could hardly under the circumstances have been surpassed. Lord Raglan at the same time added that he fully recognised the services rendered to the army and to the Boers and the natives by the voluntary associations which supplemented the efforts of the army medical staff. It will be seen that all we have contended for is officially admitted by Lord Raglan. The late Director-General was obviously not responsible for the fact that his department was, and for years had been, an undermanned department; but he nevertheless sent out all the necessary medical staff and hospital equipment which he was called upon to provide for the force originally fixed upon by the military authorities and War Office. He had no power to do more than was thought necessary at the time.

It is stated that scarlet fever has broken out on board the training ship *Impregnable* at Devonport. There are some 1250 boys on board and 100 of these have already been sent to the Royal Naval Hospital, Stonehouse.

"Audi alteram partem."

## WHO DISCOVERED SERUM DIAGNOSIS?

*To the Editors of* THE LANCET.

SIRS,—I was glad to hear Professor Gruber declare himself at his first Harben Lecture, delivered at King's College on Jan. 13th, on the question of priority in connexion with serum diagnosis. If I remember his words aright he said that he was most surprised to find people in this country giving the credit for the discovery of serum diagnosis to a foreigner when this credit really belongs chiefly to two of our own countrymen—namely, Dr. H. E. Durham and Dr. A. S. Grünbaum. The history of the discovery appears to be as follows. After some preliminary observations by Pfeiffer and Bordet, Gruber and Durham, in 1895, ascertained by extensive and careful experiments the fundamental fact that immune serum can agglutinate the bacteria concerned. This was undoubtedly the fundamental discovery upon which serum diagnosis rests and it now became necessary to apply it to the cases of special diseases. The first application was made by Dr. Grunbaum in March, 1896. Dr. Grünbaum was at the time working in Gruber's laboratory in Vienna. He applied the reaction to several cases of typhoid fever obtained from Nothnagel's clinic and obtained positive and genuine results. The first test was made on March 14th on a case of typhoid fever of 27 days' duration; the second was obtained on March 22nd on a case of typhoid fever of 11 days' duration; and the third on March 23rd on a case of 17 days' duration. All these were positive; and numerous control experiments made at the same time sufficed to establish the utility of serum diagnosis in typhoid fever and also to demonstrate the feasibility of using serum in large dilutions. Unfortunately, no more cases were available in Vienna after the third case just referred to until the following June. Meantime, on April 9th Professor Gruber attended a medical congress at Wiesbaden and announced there that positive agglutination results might be obtained by the serum of convalescent cases of typhoid fever. This announcement was made very briefly and did not mention Dr. Grunbaum's or any other person's name. Owing to the continued paucity of cases and to the wish of Professor Gruber and Dr. Grünbaum not to publish the discovery until more material had been collected no further record was put before the profession. Suddenly, however, Professor F. Widal described before the Société Médicale des Hôpitaux, Paris, some successful agglutinations by serum from typhoid patients. This was followed by a succession of papers by Professor Widal reporting many more successful cases; and the result of these publications was that Professor Widal has obtained throughout the world the credit for having discovered serum diagnosis. Owing to continued paucity of cases of typhoid fever in Vienna and to other unavoidable causes Dr. Grunbaum was not able to publish his first paper until September, 1896.

It is clear from this history, which cannot be disputed, that Professor Gruber and Dr. Durham (and perhaps Bordet)

# THE DESTRUCTOR NUISANCE AT TORQUAY

(BY OUR SPECIAL SANITARY COMMISSIONER.)

*(Continued from p. 264.)*

---

### TESTIMONY OF RESIDENTS.—THE ILL HEALTH AND ACUTE SYMPTOMS ATTRIBUTED TO THE DESTRUCTOR.—NUMEROUS AND BITTER COMPLAINTS.

HAVING given the history of the circumstances which resulted in the construction of a destructor at Torquay and the unfortunate selection of the site which it now occupies, it is necessary to consider the complaints that have been made. It was, as already stated, in September, 1898, that the burning of the town refuse commenced. Individual complaints soon followed but it took some time before the dissatisfied inhabitants began to organise more systematic protests. By the summer of 1900 the agitation against the destructor had assumed *formidable* dimensions. If reference is made to the local papers it will be found that the matter was discussed by the Marychurch District Council, which was at that time a separate local authority. Mr. G. M. Winter, M.R.C.S. Eng., then read to the council a memorial signed by from 30 to 40 ratepayers and occupiers of St. Margaret-road, St. Marychurch road, Westhill, and Daison. This memorial stated that:—

> In consequence of the injurious effects of the smoke, fumes, and gases ejected from the destructor your petitioners respectfully call the attention of the district council to the serious effects upon personal property caused by the said destructor, and request them to take steps effectually to prevent the nuisance.

Mr. Winter, according to the newspaper reports published at the time, is represented to have urged upon the council, of which he was a member, that this was a serious complaint. The matter had been brought before it during the previous month of September and representations were then made to the Torquay Council. A reply was received in the following month of November to the effect that certain alterations would be made which would effectually stop the nuisance. These alterations, however, had not secured the desired result. Mr. Winter then protested that this was in no wise a mere sentimental grievance and he regretted to notice that the officials at Torquay strove to belittle the complaints they had received. At a recent meeting of officials connected with sanitary departments which had been held at Dartmouth they had even stated that the destructor worked well and that no complaints had been received. Such a statement was not justified, for the Marychurch Council had complained, and Mr. Winter went on to say that the fumes from the destructor affected the health and comfort of the inhabitants. The smell was foul and nauseating. There was no doubt that the destructor was placed in a ridiculous position. He added:—

> No one knowing anything about wind and gases would place such a thing in the bottom of a pit, where the wind could not possibly take the fumes away. Possibly the destructor was faultily constructed, or perhaps the fumes were not properly cremated. He had said sufficient added to their own personal knowledge to show that a nuisance existed, and a very serious one which affected many ratepayers. He would move: "That the St. Marychurch District Council, recognising the real nuisance emanating from the Torquay refuse destructor, regret that effectual means have not been taken to abate it after the communication of Sept. 26th last and trust that the town council will at *once* take steps to do away with the nuisance and its attendant risk to health."
>
> Mr. C. Taylor seconded.
>
> The Chairman, Captain Hill Lowe, said the destructor was a very decided nuisance and he was exceedingly glad that the matter had been brought forward.
>
> The motion was unanimously agreed to.

In consequence of the adoption of the above resolution a deputation waited on the Torquay Town Council and were informed that the council would construct a Jones's patent coke cremator in the main flue so as to render the fumes and gases innocuous. The *Torquay Directory and South Devon Journal* of Sept. 5th, 1900, reports the discussion held by the council in regard to this deputation. A letter was read from Mrs. Ridley, of Vane Hill, complaining of the smells from the destructor, but the borough surveyor stated that on the night complained of the destructor was not at work. Councillor Pike said that he lived within 150 yards of the destructor and had never smelt it, and that sentiment was at the bottom of all the complaints. Alderman Kerswill named people living near who had never smelt anything objectionable, but Councillor F. J. Crocker admitted that there had been cause for complaint, and the discussion was brought to a close by the Mayor who declared that the cremator which they were about to build would destroy the last germ of every reasonable complaint. The local paper, after giving these details, comments on this discussion in the following terms:—

> An even worse feature was the frequent attempt to pour ridicule upon those who have addressed complaints either to the council or the public press. A lady was several times held up to ridicule, and one member went so far as to speak of ratepayers who have been prominent in the agitation about the destructor as lunatics. This sort of thing only brings the council into disrepute and is to be regretted by all who value the good name of the borough. By their action the council admit that there has been cause for complaint. Then why throw dust in the eyes of the public? And why insult those who have felt compelled to call attention to the matter?

Shortly after this the boundaries of Torquay were extended so as to include the districts of Marychurch and Chelston. Consequently the Marychurch District Council, which it has been seen was a centre of agitation against the destructor, ceased to exist, and Mr. Winter, who had been a leader in this movement, became a member of the Torquay Town Council and was thus jointly responsible with his fellow members of the council for the destructor. There were two good reasons to hope that the nuisance would be abated: firstly, the construction of the cremator, and, secondly, the fact, which has been already explained, that with the addition of a population of 12,000 there would now be refuse enough to keep the destructor working at night as well as in the day, as it was argued that the nuisance arose through the cooling down of the cells when the fires were not kept fully alight. That these hopes were not realised is, I think, fully demonstrated by the evidence I personally was able to collect.

A portion of the Marychurch road passes over one of the hills that dominate the destructor. Here my first visit was to Dr. H. Humphreys who has taken a leading part in the agitation against the destructor. To him the matter is of personal as well as of general interest. He would long since have left the district, but having purchased the freehold of his house he is compelled to remain. He could not sell his house except at a considerable loss, for he conceives that it would not be honest to do so without warning the intending purchaser of the nuisance to which he would be exposed. Some of his neighbours, however, have been less scrupulous. After taking part in the agitation against the destructor they have succeeded in selling or letting their houses and are now silent. Others are seeking to follow this example or to let out some of their rooms to lodgers and are therefore also anxious not to say too much about this grievance. But there still remain a considerable number of persons who have nothing to lose and much to gain by bringing such public pressure to bear as will result in the abolition of the nuisance. Dr. Humphreys explained that the odour varied considerably. Sometimes it seemed like the smell of a tallow candle, at other times it was more like that of a burnt shoe. It was stifling, caused a choking sensation, and there was an irritation of the throat as if produced by fine dust. The windows were dirtier than they used to be before the destructor was built. When the smell had thoroughly penetrated a room it hung about for hours after the wind had changed and the fumes of the destructor were blown in another direction. The odour was of such a penetrating character that it had been noticed at a great distance, even out at sea off Petty Tor. Mrs. Humphreys complained of a nasty taste in her mouth, of nausea followed by salivation, and of sore or spongy gums. The family were often driven out of their garden by the odour and obliged to take refuge indoors and to shut all the windows, which was very unpleasant on a hot summer day.

My next visit was to neighbours of Dr. Humphreys, the Misses Tapper, whose house overlooks the valley in which the destructor is built. They explained that they were away when the destructor was erected and on their return they were surprised to find their house invaded by strange odours. Later, when the summer came, these odours were so strong that if the wind came from the direction of the destructor they would be obliged to get up in the night so as to shut all the windows. At the risk of suffocating themselves they even shut down the dampers of their stove and closed up their fireplaces. They complained that the odour made them feel sick and provoked headaches. A lady invalid who could get fresh air only in the garden was on these occasions obliged to remain indoors. They had not only felt a sensation of nausea but this had produced nurse her hostess. After 10 days this lady (the mother) felt so ill that she returned home and went straight to bed, carefully avoiding her children; and next day it was clear that she was beginning measles. The children, meanwhile, had been threatening the troublesome cough that might precede measles, but not until the fifteenth and seventeenth day after their exposure did they show manifest signs of measles Now, it would seem that the extra dose received by the mother distinctly led to a shorter length of the incubation stage. Again in August and in the early days of September I was using lymph of the Jenner Institute (*not* the Jenner Institute of Preventive Medicine) which failed to take at all. Later, in the month of October, I found that the vaccine would take effect in a mild sort of way on the twelfth day, showing that there probably was but a very mild dose of the vaccine virus in the glycerine I had always been able to prophesy that in revaccination one could look with certainty for the local reaction on the third or fifth day (at least this always happened when I used lymph from Dr. Renner's establishment). So I took to using Dr. Renner's lymph again and always find that I can guarantee a good pock-mark or an abortive one equally surely about from the third to the fifth day, showing, I suppose, that the dose is fairly equal.

These facts would seem to prove that if lymph is over-glycerinated it is either inert or very slow in incubation, all which would show that there might be some standard of strength established by the authority of those who make lymph for the Government. For we non-public vaccinators are entirely dependent on the private companies who advertise their goods. They, on the other hand, deny all responsibility for the uncertainty of their lymph, I have lately revaccinated and caused to be revaccinated many who were done with Jenner lymph and find that 30 per cent. when done again with Dr Renner's lymph give excellent vaccine vesicles. This shows how our unfortunate patients are entirely at the mercy of the trade supply in lymph.

I am, Sirs, yours faithfully,
Courtfield-road, S.W, Jan. 21st, 1902. J. KINGSTON BARTON.

---

## EXCISION OF GASTRIC ULCER.

*To the Editors of* THE LANCET.

SIRS,—I notice that in THE LANCET of Jan. 25th, p. 275, you refer a correspondent signing himself "E N. B." to a case of mine recorded in your issue of March 2nd, 1895, p. 544. As that case occurred early in the history of operation for perforated gastric ulcer and was my first experience of operating for it, will you allow me to say that in four or five subsequent cases (one of which was published in 1896) I have not thought it advisable to excise the ulcer before suturing? I think that perhaps your correspondent may find the information he seeks in the excellent lectures by Mr. A W. Mayo Robson published in THE LANCET of March 10th (p 671), 17th (p. 747), and 24th (p 830), 1900, and in an address by Mr. Robson in THE LANCET of Feb 9th, 1901, p. 375.

I am, Sirs, your obedient servant,
Brighton, Jan. 25th, 1902. R. F. JOWERS.

---

## FIRST AID FOR PRIMARY HÆMORRHAGE: THE WRONG INSTRUCTION GIVEN TO AMBULANCE CLASSES. A CORRECTION.

*To the Editors of* THE LANCET.

SIRS,—In my letter which appears in THE LANCET of Jan. 25th, p. 256, the words "severely burnt" have been omitted from the account of the infant who was carried over two miles to a hospital.

I am, Sirs, yours faithfully,
Plymouth, Jan. 25th, 1902. C. HAMILTON WHITEFORD.

---

## FEEDING ON GOAT'S MILK.

*To the Editors of* THE LANCET.

SIRS,—If any of your readers have had experience of the suckling of children by goats I should be greatly obliged if they would let me benefit thereby. The child who has come under my care quite recently is four months old, and has been suckled since birth by a goat, taking at present four meals daily from the goat and two from the mother. The child is large, firm-fleshed, mottled, but has a scurfy patch covering the lower part of the forehead, the nose, and the left cheek. There is no irritability, flatulence, vomiting, or loss of weight. There has been a little diarrhœa which passed off without treatment; curds are frequently passed in the stools. There is no loss of weight. The udders of the goat are well cleaned before each meal and the animal is healthy.

Would it be wiser to advise a change in the method of feeding than to leave well alone?

I am, Sirs, yours faithfully,
Albareda 49, Seville, Jan. 21st, 1902. JOHN DALEBROOK.

---

## HIGH FREQUENCY CURRENTS IN THE TREATMENT OF PHTHISIS.

*To the Editors of* THE LANCET.

SIRS,—I trust that you will afford brief space for an indignant repudiation of certain sensational statements concerning the treatment of phthisis by currents of high frequency which have appeared in the columns of the daily press, and in which my name has been used to my great annoyance and entirely without my knowledge or consent.

On Jan. 23rd, as a matter of courtesy, I saw a representative of the *Daily Mail*, who called on me with an introduction from a well-known member of our profession, a personal friend, for the alleged purpose of reporting on the subject which had been dealt with in the Gresham lectures. I explained to him impersonally the *modus operandi* of the electrical treatment in question, allowing him to test for himself the physical properties of the current from an ordinary Oudin resonator which stands in my room without any adjuncts of elaborate finish, mystery, or impressiveness, and is indeed in all its surroundings eloquent of makeshift arrangements and purely experimental use. I pointed out that I personally was interested in the matter from a purely scientific point of view, and had had an extremely short and small acquaintance with its alleged therapeutic effects.

Before consenting to afford him any information I had obtained his assurance that my name should not be used at all in connexion with the matter, so that its use in the published paragraph is entirely unjustifiable and a grave breach of confidence.

I have written a letter to the *Daily Mail* pointing out my extreme annoyance, and I feel confident that those who know me and my work will at once see how I have been made an unsuspecting victim to the peculiar "principles" of modern sensational journalism.

I am, Sirs, yours faithfully,
Devonshire street, W., Jan. 28th, 1902. T. J. BOKENHAM

---

THE ROYAL UNITED HOSPITAL, BATH.—Mr. Arthur Roberts, the comedian, who was performing at the Theatre Royal, Bath, gave an entertainment at the Royal United Hospital, Bath, on Jan. 24th. Mr. Roberts was assisted by several members of his company and the performance was much appreciated by the patients.

THE ROYAL INSTITUTION.—The Friday evening discourse at the Royal Institution on Jan. 24th was delivered by Mr. H. G. Wells, the title of his address being "The Discovery of the Future." He thought that along certain lines and with certain limitations it was quite possible to forecast the future and that the time for commencing investigations in this direction had, in fact, now arrived. In support of his arguments he referred to the calculation of planetary movements many years in advance of the actual occurrences, to the predictions of chemists as to the properties of bodies which were unknown at the time but have since been discovered, to the results of medical prognosis, and to the anticipations of palæontologists at first founded on scanty data but afterwards verified when more abundant fossil remains came to light. The human race as at present existing was not, he said, the last stage in the evolution of the highest form of animal life, and speculation as to what type of creature would succeed man on the earth was exceedingly interesting. He believed that within the next few hundred years the human mind would undergo great development and would accomplish things compared with which all its achievements in the past would be only as the dawn before the day.

## BIRMINGHAM

(FROM OUR OWN CORRESPONDENT )

### *A Rowton House*

A PRACTICAL attempt to solve the difficulties of the housing question among the poor of Birmingham has just been made by the promotion of a Rowton House scheme. It is announced that a company (the "Rowton Houses ') has been formed with a capital of £50 000, in ordinary shares of £1 each, to further this object. It is stated in the prospectus that no contracts have been entered into, that none of the capital has been underwritten, and that no promotion money will be paid "Rowton Houses,' if carried out, will supply a great social want especially among the artisan class and if successful will materially relieve the pressure in the overcrowded parts of the city At the same time it is estimated that it should be a financial success if the project is realised on the lines laid down by the promoters One house will be first erected capable of accommodating 600 men, for which the charge will be 6*d* per day , this includes for the 24 hours, separate sleeping accommodation the use of cooking ranges and appliances, dining smoking and reading rooms library, and foot-baths, unlimited use of hot and cold water, and, at nominal charges, the use of a locker and hot and cold baths Surely this is a tempting programme to a working man not *only to wash and be clean but to enjoy comforts, and even* luxuries which it is at the present time beyond his power to possess From a health point of view the scheme is deserving of all the encouragement and support that can be given to such a praiseworthy object

### *Hospital for Children*

On Jan 27th the annual meeting of the governors of this institution was held under the presidency of Mr C F Matthews In the report which was read (the forty first) it was stated that during the past year the number of in patients treated had been 943 of out-patients 15 451, and of casualties 264 The death rate calculated on the in patients had been 7 08 per 1000 as compared with 7 9 per 1000 on 1060 patients in the previous year The expenditure had exceeded the income by £307 The chairman gave some interesting figures comparing the hospital with its position 40 years ago, stating that the governors now had £20,000 invested compared with nothing at that time. Various votes of thanks were passed

### *Sanatorium for Consumption*

Some discussion has arisen in the county of Worcester as to the proposed plan to establish a sanatorium for consumption A protest has been issued by the ratepayers of Malvern, in which they desire to submit to the county council that however desirable it may be to establish a sanatorium for the open air treatment of consumption in Worcestershire—which in the absence of the information which ought to be, but is not, at the disposal of the ratepayers is neither affirmed nor disputed—no such charge as the maintenance of the sanatorium ought under any circumstances to fall upon the rates It is considered that the object is a national rather than a local one, and the ratepayers' association deems that the expenses should not be allowed to fall upon the already overburdened ratepayer From an argumentative point of view there is much to be said upon the question but it would be well to bear in mind that the greatest good to the greatest number should influence public opinion and practical philanthropy

### *An Interesting Adulteration*

"Self raising flour is a common form of advertisement in describing the qualities of flour sold at many shops and places. It is in itself a misnomer, the effervescent qualities being produced by the admixture of certain chemicals In a case tried at the Dudley Police court on Jan 22nd the point was raised with regard to a sample taken of the flour in question which contained a quantity of potato starch and 63 grains per pound of tartaric acid with 26½ grains per pound of bicarbonate of soda In proportion to the bicarbonate of soda the quantity of tartaric acid was double what was required It was stated that the acid was really cream of tartar and the presence of potato starch was denied. Much expert evidence was called for the prosecution and for the defence, and this evidence, as usual varied considerably. In view of this difference the bench decided that a sample should be sent to Somerset House and adjourned the case accordingly The decision is looked forward to with interest.

Jan 28th

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT )

### *Salford and Small Pox*

AT their next meeting the Salford Town Council will be asked by the Health Committee to proceed at once with the building of the small pox hospital A site was secured several months ago at Drinkwater Park, and the scheme was submitted to the council, but held over for six months, as it was thought that Manchester might cooperate with Salford However, Manchester did not agree to the financial proposals and nothing has been really done by either council Possibly the recrudescence and threatening aspect which small pox has assumed may quicken the action of both councils in providing isolation hospitals

### *Mid Cheshire and Vaccination Charges*

With small pox threatening the country at large it seems a curious time to complain of expenditure on vaccination , but at the meeting of the Northwich Board of Guardians on Jan 24th "Mr J Holland appealed for retrenchment and economy ' He said that the charges under the Vaccination Acts were £280 a year more than they were 10 years ago He said that in the rural districts money was hard to get, &c , and 'that steps should be taken to get rid of the present system It is not clear from the report whether or not he would put a stop to vaccination, but as he wishes for economy he had better study the statistics of expenditure in those places that have suffered from even a slight invasion of that loathsome and dangerous disease small pox

### *The Royal Eye Hospital*

At the annual meeting of the subscribers to the Manchester Royal Eye Hospital held on Jan 23rd it was stated that at the hospital in Oxford street 10,736 out patients were admitted during the year, and 12 237 at St John street, a decrease of 1162 on the previous year The in patients at Oxford street were 1334 being 22 fewer than in 1900 The excess of expenditure over income which is so common with hospitals, was a little under £30 The Lord Mayor, who presided said that the decrease in the number of patients treated looked as if the hospital had overtaken the requirements of the district. The accident cases showed an increase, and this had been going on for several years Many of them were from bits of iron chippings getting into the eye, which is not to be wondered at, as there are so many iron and engineering works in the district A pleasing instance of gratitude was mentioned at the meeting More than 30 years ago a young man was treated at the hospital, and his elder brother Mr A. Greenhalgh, wrote to the board saying that he should never forget the kindness and courtesy of Dr D Little who was then house surgeon and that he had determined when he had the ability, to subscribe to the funds of the institution, and he said, 'I have now pleasure in sending you a cheque for £1000 '

### *Poisonous Preservatives in Milk*

One of the inconveniences resulting from the advances in chemistry and the spread of knowledge is that various articles of food become more and more 'suspect' from objectionable methods of applied science Two milk-dealers were summoned at the instance of the Lancashire County Council, on Jan. 21st, to the county police-court, Strangeways for selling milk containing an injurious ingredient.' It was found on analysis to contain one part of formaldehyde to 100 000 parts of milk. Mr Wingate Saul, who prosecuted said that the county council was very anxious that the practice of adding formaldehyde to milk should be stopped and the committee appointed by the Local Government Board had advised its complete prohibition Some people said that it might be hard on the retailer as it could not be proved that the wholesale dealer did not put the formaldehyde in There was a suspicious point, however, against the retailers if it were true, as Mr Saul understood it to be that travellers go round and sell formaldehyde to them for it would scarcely be bought unless it was used A fine of 20*s* and costs was imposed in each case Mr Yates K C. the magistrate, asked if these actual vomiting. In the Shirburn-road Mrs. Hill told me that she slept in a little house-boat on the Dart so as to escape the fumes and only came up to her house so as to attend to the fruit and other matters. When at home she lost her appetite and suffered from dryness and irritation of the throat. The smell seemed to her like the burning of old shoes; the air felt oppressed and as if there was not enough of it. This gave Mrs. Hill a pain that commenced at the back of the head and then spread to the front and especially over the eyebrows. Mr. Hill, being absent when I called, sent me a written statement in which he says that the odour, "especially at night, is absolutely unbearable. The smell is peculiar and quite unmistakeable. It resembles somewhat that which would be caused by a smouldering greasy rag in a small confined room in which there was also present a bucketful of coke fire and a handful of brass chips being dissolved in aquafortis." Returning home late at night from sea he found the atmosphere about his house "so dreadful" that he doubted if he could exist in it till the next morning. "In fact, my wife and I have often passed many nights on board of our yacht in the harbour between our long cruises rather than return home and be poisoned." Mr. Hill adds: "It is interesting to note that while there is apparently very little brown smoke issuing from the destructor stack when viewed from the shore, yet from the sea at a distance of a few miles, when the destructor can be seen against the dark background of the hills, there always appears an impalpable blue vapour which extends for miles, tending ever downwards until it merges into the thin haze which is always present more or less in the valleys of the town if the wind is in that direction."

Miss Leney of Bronshill-road explained that at first she did not notice the smell very much, but it was very bad in the winter of 1900 and in April and May. The previous year Miss Leney was away at that time. The odour made her retch and produced pains in the abdominal region. On one occasion she awoke at 5 A.M. with a sensation of swelling in her mouth. It was necessary to close all the windows and her sister was nearly sick. Miss Leney soon felt so depressed and anæmic that she consulted her medical attendant, with the result that she determined to leave Torquay for a while, and then she speedily recovered. This was all the more distressing as four years ago Miss Leney bought her present house and came to live at Torquay on account of her health, and at first the place agreed with her very well. Now she can only keep herself in health by occasionally leaving Torquay. Last August when entertaining friends in her garden all the guests had to rush indoors and shut the windows in spite of the heat on account of the odour that came upon them. Formerly they would live in their garden up to 10 o'clock in the evening and this was the chief charm and benefit of the place. Now they had to go indoors and shut all the windows. Some persons, I was told, say they can notice the destructor smell when they wash their faces if the water is taken from a cistern placed in an exposed position.

The owner of a little shop in the Marychurch-road told me that at times she felt inclined to tie a handkerchief across her face. Many of her customers complained of the smell and inquired as to its cause. It was generally worse in the evening and produced a sensation of sickness. Entering another shop close by I heard much the same complaint. Other shopkeepers in this neighbourhood, either because they are less sensitive or because they fear to injure their business interests, strive to belittle the grievance, and some even declare that they do not notice the smell at all. But Mr. Taylor, who lives in the same road, stated that he had seen people going about holding handkerchiefs to their noses, and that on one particular Wednesday the odour was so bad that several people declared that they would have to leave. Several visitors lodging in the neighbourhood had got up in the night thinking there was a fire or that the drains were out of order, and had to be pacified by their landlady. Two persons living in Sudbury-terrace stated that they had to bar their doors and windows in the hope of keeping the smell out. A medical practitioner described the smoke as of three colours, black, brown, and pearl-grey. It made him sick, ill, and cross, and, he added, "we doctors have quite enough to irritate us without that."

Mr. H. Bedford of Shirburn-road called on me and also sent me a written statement. This gentleman was so much affected that he had appealed to the Local Government Board offering to bear witness and to be medically examined. "I am described," says Mr. Bedford, "by the medical men I have consulted as physically strong and without any organic disease and have been advised by them that my only remedy is to leave the neighbourhood." When possible he had done so and his symptoms gradually subsided, but returned again when he came back to Torquay. These symptoms, Mr. Bedford writes, are constant nausea, giddiness, and headache, with darting pains following on the breathing of the fumes. When there is no odour he is oppressed with a nervous dread lest it should return. He complains further of swollen lips, a bearing-down sensation in the legs, a sense of suffocation, and general physical prostration. Mrs. Bedford, however, though living in the same house, is not so sensitive. This lady is inconvenienced but feels no acute symptoms. Another complainant, Mr. Wilson, who lives at Marychurch, told me that he had spent the greater part of his life in Canada where he had practical experience of the malodorous skunk, but he thought that the fumes of the Torquay destructor were worse. He was convinced also that this odour did not readily mix with the atmosphere. Thus, when the wind changed and the air became pure again he found that after opening his doors and windows the smell was still perceptible in the corners of his rooms. If this is correct it is important, for it would show that the fumes come in a comparatively compact volume instead of being diluted by expansion. They gave Mr. Wilson pains in the head, temples, and throat. In her youth Mrs. Wilson had been struck by lightning and this had deprived her of her sense of smell, but she felt the fumes in her throat and they produced a sense of sickness. Mr. Heavens related that he remembered the old refuse deposit near Windmill Hill, and the nuisance caused by the rats, especially in the neighbourhood of the racecourse. But it was easier to keep the rats away than the fumes of the destructor, and he was obliged to keep his windows shut in the hot summer days. Following upon an attack of typhoid fever his sister had suffered greatly from indigestion; but when she went to stay with some friends living near the Bristol Channel she felt much better. On her return to Torquay, however, a relapse occurred. Her medical attendant treated her for dyspepsia, but still she could not recover her appetite. At last she went to London and resided at Balham. In two days she recovered and was quite well again. Torquay is supposed to be a health resort and yet here is a case of a patient who only recovers on going to London. A neighbouring family named Bolton gave notice and left their house in consequence of the nuisance, but most of the residents are leaseholders or freeholders and cannot get away. It used to be most enjoyable to sit out in the garden and benefit by the cool breezes coming from the vast expanse of moorlands that stretch north of Torquay. But as the destructor is in this direction when the wind blows from that quarter those persons who are susceptible dare not sit out in their gardens.

Finally, I went to the Roman Catholic convent at Marychurch. Here there are 70 orphans, eight servants, 26 young lady boarders, 30 sisters, and a day-school. The late lady superior had signed a petition against the destructor. Several of the sisters had complained and the lady superior who received me said she was under the impression that the general opinion was that the destructor was a serious nuisance. Had I continued these visits I could have collected much more evidence of the same description, but doubtless the above will suffice to give a general idea of the sort of complaints which were made. Of course, it will be said that they are grossly exaggerated, and in some instances wholly imaginary, and that other witnesses could be produced who have no complaint whatsoever to make. But it must be borne in mind that many persons are materially interested in striving to minimise the grievance. It is quite certain that there would never have been so much agitation, so many petitions presented, and so many complaints made if there had been no nuisance whatsoever. The very efforts made by the Torquay Town Council to alter and to improve the working of the destructor prove that the existence of a grievance is acknowledged. It remains for me to describe the latest modifications that have been made in the construction of the destructor. Then I will attempt to point out how the difficulties which have arisen at Torquay are of great interest to all towns which have to face the problem of refuse disposal.

(*To be continued.*)

there was a population in these three counties of 284 000 persons

### *Cardiff Workhouse*

Hitherto the resident medical officer at the Cardiff Workhouse has acted as dispenser to the institution, but the board of guardians recently decided to appoint a separate officer Among the nine applicants for the position were four ladies one of whom has been elected to the post at a salary of £30 per annum

### *Rabies in Pembrokeshire*

A case of rabies has occurred among the foxhounds belonging to the Pembrokeshire hunt The pack is kenneled near Haverfordwest, and on Jan. 15th the dog affected attacked a group of persons in the town, tearing their clothes and, in the case of a boy, aged nine years, inflicting a wound on his forehead The dog, which was secured, died on Jan 20th, when its brain was sent to the Brown Institution for examination The boy went to Paris on Jan 21st for treatment at the Pasteur Institute

### *Duties of Poor-law Medical Officers*

At a recent meeting of the Helston Board of Guardians a discussion arose in reference to some of the medical officers neglecting to send to the meetings of the guardians their reports of attendances on pauper patients Eventually one of the members gave notice of a motion that in contracts with the medical officers a clause should be inserted to the effect that the medical officers would be debited with a sum of money for each omission to send in their report At the meeting on Jan 18th the proposition was brought before the guardians, but the clerk expressed his belief that the Local Government Board would not sanction such a clause and the motion was not seconded

### *Vaccination Prosecution.*

At Truro Police court on Jan 20th a man was summoned for disobedience to an order made by the court for the vaccination of his child Evidence showed that when the police attempted to enforce a warrant of distress the defendant locked the door and defied them Eventually he was fined £1 and in addition was ordered to pay costs and advocates' fees or to undergo a month's imprisonment. He preferred the latter alternative and becoming noisy was removed from the court, protesting that he was the victim of a conspiracy

(FROM OUR OWN CORRESPONDENTS )

### *Glasgow Royal Infirmary*

THE annual report of the Glasgow Royal Infirmary, which was issued on Jan 25th, contains in addition to the usual statistics an allusion to the proposed reconstruction scheme which has for so long been in a state of suspended animation A determination is expressed to adhere to the larger proposal to rebuild the entire hospital at an estimated cost of £250,000 As the sum already in hand amounts only to £80,000 a balance of £170 000 is still required The managers explain that in view of the numerous other appeals which have been made to the public they have deemed it advisable to postpone their own claims, but they indicate that ere long the question will assume an active phase The report contains an appreciative note of the services rendered by Dr Moses Thomas who retires from the position of superintendent after a tenure of office extending to 34 years In the financial statement attention is drawn to the fact that the ordinary expenditure for the year exceeded the income by upwards of £10,000 and that the managers have been compelled to draw to this extent on the capital account.

### *Small-pox in Glasgow*

The total number of small-pox patients now in hospital is 58 Four new cases were notified on Jan 26th

### *Scottish University Students*

The annual conference of the Students' Representative Councils of the Scottish Universities has been held in Glasgow during the past week. Principal Story, in welcoming the members made reference to the proposed rearrangement of the academic year, and described the proposal to substitute three terms in each year for the present prolonged session as one needing careful consideration by the students themselves, the question whether such a change was adapted to the circumstances of the students was one of vital importance The Principal also alluded to the Carnegie bequest and stated that it was within his knowledge that applications had been made for the payment of fees by those whose circumstances rendered them altogether unsuitable for such assistance he advocated the cultivation of a healthy public opinion on this point Among the various subjects discussed by the conference was the reorganisation of the medical curriculum and a unanimous vote was recorded in favour of a rearrangement of certain of the subjects of the institution of three terms of 11 weeks each instead of the present winter and summer sessions, and of the complete removal from the fifth year of all classes other than those involving clinical work It was also decided to request the senates of the several universities to institute two final examinations for graduation in medicine in each year —The Liberal students of the University of Glasgow have announced the name of the Right Hon John Morley, M P, as their candidate for the lord rectorship, the election to which will take place in November

## IRELAND

(FROM OUR OWN CORRESPONDENTS.)

### *University of Dublin*

A MEETING of the Senate of Dublin University was held in Trinity College on Jan 25th for the purpose of electing a representative for the "Classis Quarta" in the place of the late Dean of St. Patrick's Cathedral Sir John William Moore and Mr William Cotter Stubbs were nominated to fill the vacancy, and it was announced that ballot papers would be sent out as soon as possible

### *Danger of Small-pox in Dublin*

A letter from Sir Charles Cameron, C B, the medical superintendent officer of health of Dublin, has recently appeared in all the Dublin daily papers warning the public to take every possible precaution against attacks of the loathsome disease of small-pox, and earnestly requesting all who have not been revaccinated and who are over 12 years old "to have that trifling (as regards pain or inconvenience) operation performed on them as soon as possible" As already stated in THE LANCET, if small-pox should come to Dublin as an epidemic there exists no suitable place in which its victims could be treated, the recommendation of the Cadogan Commission, that an isolation hospital should be provided for it outside the city boundary, having proved inoperative

### *The Nursing in Armagh Workhouse*

The Local Government Board has written to the Armagh Board of Guardians requesting them to comply with the terms of the order of Dec. 4th, 1901, and to appoint, as soon as practicable, a qualified nurse and two wardmaids for duty in the infirmary The matter was, on Jan 21st, at a meeting of the Armagh guardians, referred to the special nursing committee of the Board who are to report

### *County Antrim Infirmary*

The friends in Lisburn of this most useful institution are making strenuous efforts for the coming bazaar and with this object a conversazione was held on Jan 21st.

### *North of Ireland Branch of the British Medical Association*

The winter meeting of the North of Ireland Branch of the British Medical Association was held in the Belfast Museum on Jan 23rd the President, Dr J S Darling, being in the chair Mr Robert Campbell read notes on the Operative Treatment of Hernia in Children and showed specimens illustrating the anatomy of spina bifida, talipes equino-varus and genu recurvatum Dr J McLiesh read notes of a case of Lymphatic Leukæmia with a condition of skin resembling pityriasis rubra, and showed a specimen of Pneumothorax lasting six months and one of Loculated Empyema. Mr H. Norman Barnett read notes of two cases of Bubonic Plague occurring on Board Ship and showed photographs and microscope slides illustrating his paper Professor J W Byers and Professor T Sinclair gave details of a case in which a Volvulus of the Sigmoid Flexure causing Intestinal Obstruction had been twice successfully relieved in the same patient at intervals of four years by abdominal section Mr G L St. George (Lisburn) showed two cases of Spina Bifida, both successfully treated, one by Morton's fluid and the other by excision Dr T A Vesey (Rostrevor) read notes travellers could not be proceeded against for a misdemeanour for selling the drug, and Mr. Saul thought they could, "as it was an irritant poison."

*The Christie Library.*

The department of the Christie Library, Owens College, which has recently been enriched by the gift of Mr. Christie's own collection of books numbering nearly 7000, was formally opened by his brother, Mr. Hector Christie, on Jan 22nd. It is the library of a scholar and though not appealing specially to busy practitioners passing and re-passing day by day, these may sometimes heave a sigh of regret that their avocations prevent them revelling in its treasures, like Professor Wilkins, who said that Mr. Christie's favourite study was the period of the Renaissance of classical learning. It is specially rich, among other treasures, in editions of Horace, the collection of which was one of Mr. Christie's hobbies.

*The "Triplets."*

The feeling in favour of the disintegration of the Victoria University grows apace. Liverpool and Yorkshire are in earnest as to each having a university of its own. Manchester would no doubt have remained content with the *status quo*, but now, seeing that the break-up is inevitable, she looks to the future without dismay. The graduates of the Victoria University, however, are disturbed as to the effect these impending changes may have upon the value of their degrees, and it would be unjust as well as unfortunate if they should suffer. Each of the disintegrating colleges is animated by the highest regard and affection for the others, with whom, however, it is impossible to remain associated any longer, and as the parting is to be accomplished with goodwill all round it is to be hoped that there may remain something of a "triple alliance."

*A Park for Hyde.*

The town of Hyde has just received the munificent and specially valuable free gift of a park of 30 acres of grass-land and shrubbery as a pleasure ground for all time. It was offered in the Diamond Jubilee year by the Misses Ashton, of Little Onn, Staffordshire, with certain conditions, however, that the corporation felt unable to accept. All difficulties have now, happily, been overcome and Hyde will have its park. There is a roomy mansion which would serve for a museum or art gallery. Anyone who knows the cheerless aspect of such manufacturing towns as Hyde, with their smoke-begrimed, mean-looking, dingy streets will be able to appreciate the value of such an open space to the inhabitants. The gift is valued at £10,000, and perhaps the corporation may spend on it a like sum.

*A Pest-house.*

It may perhaps be worth while to put on record the following revolting and deplorable case as an illustration of the difficulties sometimes met with by those who are striving to safeguard the public health. At Barrow, on Jan. 17th, a man was sent to prison for four months for neglecting his eight children, and a man and wife living in the attic of the same house were each sentenced to two months' imprisonment. The first set of children were in a dreadfully filthy condition and practically starving. The house had only five rooms and 23 people lived in them. Mr. J. Settle, the medical officer, said that the small-pox epidemic broke out there. "The family were all unvaccinated, and owing to the outbreak of small-pox in the house the disease spread to no fewer than 30 people in the town, and it might just as easily have spread to 30,000. Through these people it was carried to Staffordshire and Blackburn. The authorities put new furniture and bedding into the house, but these were soon in as filthy a condition as those destroyed" What chance is there for children brought up in such surroundings?

*Rainfall in 1901 at Longdendale and Thirlmere.*

At Longdendale, from which valley the whole supply of water for Manchester came till 1894, the average daily contribution last year was 21,922,260 gallons. The total rainfall was 40 01 inches. From Thirlmere the average daily quantity was 8,353,284 gallons. This was more than that of previous years, but as the pipe has a capacity for the passage of 10,000,000 gallons daily it shows that there is serious leakage. The rainfall for the year at Thirlmere was 74·3 inches, as compared with an average of 86·2 for the same locality during the last 25 years. The sooner that Manchester completes the second pipe from Thirlmere the better.

Jan. 28th.

## WALES AND WESTERN COUNTIES.

(From our own Correspondents.)

*Penmaenmawr Isolation Hospital.*

North Wales is not at all well provided with isolation hospital accommodation, though the Llandudno and Colwyn district councils have set a good example in this direction. The Urban District Council of Penmaenmawr, where there is a population of 3500 persons, has decided to erect a hospital on the mountain side at a cost of about £4000. There will be a separate administration block and two pavilions with accommodation for 12 patients, and two diseases can be treated at the same time.

*Society of Medical Officers of Health.*

At the meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health held at Bath on Jan. 22nd, Dr. W. H. Symons (medical officer of health of Bath) opened a discussion upon the Distribution of Phthisis. He stated that the death-rate from phthisis in Bath had fallen from 2·5 per 1000 in 1867 to 1·1 in 1900 and that while the death-rate of Bath among females had always been lower than that of England and Wales, among males the former had always exceeded that of the rest of the country. The advantages of sanitary surroundings were strikingly shown in a selected locality of Bath where a private improvement scheme was carried out nearly 20 years ago. During the 10 years prior to the demolition of the insanitary dwellings there were 84 deaths from consumption; in the next decade, when the improvements were being made, there were 31 deaths; and in the last 10 years there were only five deaths. When commenting upon the statement that the highest death-rate from phthisis among the counties of England and Wales was in Cardiganshire and the lowest in Monmouthshire and Rutland Mr. J. Tubb-Thomas (medical officer of health of Wiltshire and formerly of Rutland) expressed the opinion that the low mortality in Rutland was in great measure accounted for by the excellent sanitary condition of the county, and he said that phthisis only prevailed in those portions of the county where insanitary surroundings existed.

*Small-pox in Bristol.*

Bristol has been singularly free from small-pox during the past few months, although it is open to attack either through land-borne or sea-borne travellers. There was one case in December, 1901, the patient in question being discharged from the hospital ship in the middle of January, and a man who had lately come from Boston, Massachusetts, died from the disease on Jan. 7th, having only arrived in Bristol on the previous day. The isolation accommodation is quite insufficient for the needs of the city. The Novers Hill Hospital, which may be used for small-pox, is habitually full with convalescent scarlet fever patients from the Ham Green Hospital where extended accommodation is urgently required.

*Notification of Pulmonary Tuberculosis.*

The Llangyfelach Rural District Council has decided to invite notifications of cases of pulmonary tuberculosis occurring within the Llandilo Talybont portion of their district.

*Inquests in Public-houses.*

The standing joint committee for the county of Brecknock has given instructions that whenever practicable coroners' inquests shall be held elsewhere than in public-houses.

*New Isolation Hospital in Somersetshire.*

It is proposed to establish a joint isolation hospital for the borough of Chard, the urban districts of Crewkerne and Ilminster, and the rural district of Chard. The total population of these four districts is nearly 25,000.

*Small-pox near Swansea.*

Two more cases of small-pox have occurred which are traceable to the patient who travelled from London to South Wales at Christmas, making 10 cases altogether. One patient is in the Swansea Hospital and the other is at his home in Ystalyfera.

*New Home for Inebriates.*

The Carmarthenshire County Council has decided to take steps to establish a home for inebriates in conjunction with the counties of Cardigan and Pembroke. At the last census and thus are interested in the continuance of the conflict, came to the assistance of the members. The system adopted was as follows. The compound medicines, the sale of which is by law exclusively reserved to the licensed pharmacies, were either purchased from them by the proprietors of the unlicensed drug-stores and the price afterwards recovered from the clubs, or money was advanced to the members who were thus enabled to buy what they wanted from the licensed pharmacies. The inconveniences are, of course, very great for all parties concerned, whether clubs, pharmacies, or medical officers. Attempts which have been made on several occasions to settle the question have hitherto been without success. The pharmacies are now willing to allow a discount, but they require that the club members shall cease to purchase from the unlicensed druggists—a stipulation which has caused negotiations to fail, because the clubs decline to forsake the unlicensed druggists who are their most useful allies in the campaign. It remains to be seen whether the Government, which has the control of pharmacies as well as of sick clubs, will interfere. There is at present but little hope of a voluntary agreement being arrived at.

### *"Christian Science" in Berlin.*

The craze which has for some time been known as "Christian Science" in America and England has at length been imported into Germany. Several Berlin periodicals have announced that the apostles of Mrs. Eddy have arrived in Berlin and that they have already a fine practice, especially among the classes who, from want of knowledge of the elementary principles of natural science, have been, and will continue to be, victims of any clever impostor. It is stated that the Christian Science consultation rooms are frequented by the upper classes, the nobility included, and that at certain hours of the day many carriages may be seen waiting at the doors. The subject will be discussed in the municipal council because the believers in Christian Science use for their evening meetings the great hall of a municipal college. One of the members of the council has therefore asked the mayor and magistrates of Berlin whether they will take measures to prevent municipal premises from being used for such a purpose. The medical press is also devoting some space to the subject, and in the *Deutsche Medicinische Wochenschrift* Dr. Sobotta has drawn attention to the mischief worked by Eddyism in England and America, where the number of "the faithful" is now rapidly decreasing. Meanwhile orders have been given by the mayor that municipal buildings are no longer to be used for the holding of "Christian Science" meetings.

### *Rats and the Bacillus of Danysz.*

Dr. Abel, a medical officer of the city of Hamburg, has published in the *Deutsche Medicinische Wochenschrift* an account of his attempts to destroy rats by means of the bacillus of Danysz Some years ago Dr. Danysz of Paris discovered a bacillus which has been called the bacillus typhi murium (Danysz) It is strongly pathogenic for rats and, according to its discoverer, may be used instead of other poisons to kill these animals Dr. Abel obtained cultures of it from Dr. Danysz himself, and administered portions of them in the laboratory to grey and white rats, the result being that the animals died in from six to 12 days. The necropsy showed enlargement of the spleen, swelling of Peyer's glands, partial necrosis of the liver, and the presence of the bacilli in all the organs. Other rats were then fed with the livers and spleens of the first series with an equally lethal effect. In this way the toxic action could be continued through six generations. The method was then practically used to destroy rats in some localities where they happened to be abundant, pieces of bread treated with cultures of the bacilli being laid down. The localities selected were the premises of the municipal institution for disinfecting, a large transatlantic steamer, stables accommodating from 30 to 40 horses, the depôt of the customhouse, and another large building used for storage purposes. The results presented considerable variety, being most effective in the stables where the rats completely disappeared for one and three-quarter years In the steamer and in the stores there was no apparent effect, whilst in the customhouse and in the municipal establishment the number of rats was reported to have considerably decreased. It was remarkable that very few dead bodies of rats were found, even in the instances in which the most effect seemed to be produced. Dr. Abel considered that the method, though not invariably efficacious, was worthy of a trial, and that it might be valuable when plague was imminent and when rats had to be destroyed as much as possible.

Jan. 27th.

# Obituary.

## PROFESSOR HUGO VON ZIEMSSEN.

OUR Berlin correspondent writes:—Dr. Hugo von Ziemssen, professor of clinical medicine in Munich University and one of the most popular men in the city, died there on Jan. 20th. He was born in Greifswald, Pomerania, in 1829, and studied medicine at the universities of Würzburg, of Berlin, and of his native town, where he graduated in 1854 In 1856 he was recognised as *privat-docent* after having been an assistant at the Greifswald Medical Clinic In 1863 he was appointed ordinary professor at Erlangen University and in 1874 at Munich University, where he remained till his death. His works are very numerous. When still in Greifswald he published essays on complications of measles, on diabetes, and on electricity in medicine. Afterwards at Erlangen and Munich he studied the cold water treatment of enteric fever, gastric ulcer, Bright's disease, &c. Considerations of space prevent an enumeration of all his works, as there were, in fact, few subjects connected with clinical medicine on which he did not write. He was also the editor of two great encyclopædias—the "Handbook of Special Pathology and Therapy," and the "Handbook of General Therapy"—consisting of articles written by the leading clinical teachers of Germany, and in which the chapters on croup, on epidemic meningitis, and on the diseases of the œsophagus were contributed by himself. He also, in association with his friend the late Professor von Pettenkofer, edited a "Handbook of Hygiene." Both of them did much to improve the health of the towns where they lived—Professor von Ziemssen especially by reorganising the Munich General Hospital and by founding homes for convalescents and for consumptive patients. Engrossed as he was in his literary work, in his enormous practice as a consultant, and in his duties as clinical lecturer he was nevertheless not unmindful of the general interests of the medical profession and on various occasions he took part in the meetings of the German Practitioners' Association.

## METCALFE JOHNSON, M.R.C.S. ENG., L.S.A., J.P.,

SURGEON-MAJOR, MILITIA MEDICAL DEPARTMENT.

THE death of Mr. Metcalfe Johnson, which occurred on Jan. 18th, has removed the oldest member of the profession in Lancaster, who, although nearly 79 years of age, possessed a wonderfully bright intellect and genial humour. He was the son of a medical man and was born at Wisbech in 1823. Writing of his father he said: "He was an ardent student of dietetics, and I recollect a corn-mill which he had erected in his back-kitchen, where he ground wheat by a large hand-mill and had biscuits made from the proceeds which were so hard as to require a hammer to break them. On these and water he was living at the time of his death—perhaps not the best diet for a man attending cholera patients. He was a daring inventor and at the time of his death—which took place in 1836 from Asiatic cholera—he owned a piggery of over 1000 pigs from which he expected to supply salt pork to the navy by injecting into the arteries or veins of the animals strong acetic acid."

In 1838 young Johnson was apprenticed to Dr. Muriel of Ely and he went to Guy's Hospital in 1843. Amongst his fellow-students was Sir Samuel Wilks and the friendship thus begun lasted for the rest of his life. In 1845 he was given a free dressership, his house surgeon being Mr. Cock. He became qualified in 1846 as M.R.C.S. Eng. and L.S.A., and at once bought a practice in Lancaster where he settled down. Shortly afterwards he was appointed medical officer to the workhouse and later police surgeon. In 1852 he was given a commission as surgeon to the 1st Royal Lancashire Militia, subsequently promoted to be surgeon-major, and then put in medical charge of the regular troops stationed at the depôt. In Lancaster he formed the acquaintance of Richard Owen and they were on terms of intimate friendship for many years He was at one time a prolific writer and articles by him appeared in THE LANCET entitled "Borderland, a Study of the Relation of a case of Pernicious Anæmia treated successfully by Anti-streptococcic Serum. Interesting discussions followed the reading of these communications.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Illness of Professor Duclaux.*

PROFESSOR DUCLAUX, the Director of the Pasteur Institute, has just been struck down by an attack of hemiplegia. In the middle of a lecture he experienced a sensation of vertigo which gradually increased in severity. He sat down and, feeling himself getting worse little by little, wrote on a piece of paper the word "hemiplegia." He then lost consciousness and was taken to his home where he lay for many days in a very critical condition. At present, however, he seems to be on the high road to recovery. It is a curious coincidence that Pasteur himself fell a victim to the same malady when he was in the midst of his work on the diseases of silkworms. The research was finished by his pupils. For many months Pasteur was ill, and for the remainder of his life he was partially paralysed on the right side and could only write with difficulty. However, he lived for 25 years longer, dying eventually from bronchopneumonia.

### *Milk Adulteration in Paris.*

The daily press has just undertaken an active campaign against the custom of milk adulteration which has reached enormous proportions, and the various reporters of the different journals have brought to light some extraordinary facts which have created great excitement. Milk is adulterated everywhere—at the farm, by the wholesale agent who buys up milk from the different farms, then by the milkmen who take the cans from the railway-stations to the various retail dealers, and then by the retail dealers themselves in their shops. The most common method of adulteration is that of adding water, and, as the water comes from anywhere, say, from dirty streams or from ordinary public standpipes, it is not astonishing that milk has become the vehicle for the dispersion of a number of infectious diseases. During the night the reporters have seen milkmen stopping their vans at a public standpipe and drawing water from this and pouring it into the milk-can, while the vans carry various empty cans which can be filled up with the milk which is thus increased in bulk. Seals of wax or of lead put on the cans at the point of departure are but an illusory protection, for the milkmen have made false ones copied from the real ones, which they put on. Better still, from their point of view, so as to escape the surveillance exercised by policemen who look after every milk-van which stops at night near a public standpipe, the milkmen have organised a sort of syndicate, and have confederates posted at the corners of dark streets or in gateways. These confederates, as the van drives through, throw in receptacles full of water prepared beforehand which is mixed with the milk while the van continues its journey. The Municipal Chemical Laboratory, which looks after the analyses of food products consumed in Paris, has started an organisation of its own to supervise these frauds. Every night various chemists betake themselves to the railway-stations at Paris, board the railway vans on the arrival of the trains, and seize a certain number of samples either directly from the train itself or from the milk-vans which have already been loaded up. These samples are taken to the laboratory and analysed and legal proceedings are at once taken against the senders of any milk which is adulterated; but, as it is not possible for them to go to every station at once, the chemists and their assistants start every night from the Prefecture of Police and go to some particular station pointed out by the head of the laboratory. However, the syndicate of milkmen possesses a large number of accomplices who wait before the door of the Prefecture of Police, and as soon as the chemists start in their carriage, these agents rush off on bicycles to the station to be visited, and arriving before the chemists, warn the milkmen, so that the chemists find nothing but samples which are quite irreproachable. The authorities of the Municipal Laboratory are now going on another tack, and their chemists will start each evening at midnight from their own houses for a destination which has been pointed out to them by telephone at the moment of starting. But, despite every precaution, the number of samples found to be defective is enormous, and the reasons for this are many. The chief of these is the very inadequate penalties inflicted by the courts. Out of 700 samples of milk declared to be adulterated by the Municipal Laboratory the law took no note of 500, and those persons who were found guilty were sentenced to altogether insignificant penalties, such as a paltry fine of some 10 francs. The milkmen are well organised, and when any of their number is fined a whip round is made to pay the money. If after they have been fined several times they are sentenced to two or three days in prison the syndicate pays their wages during the time that they are in prison. When the prosecuted adulterator happens to be a large commercial firm the sentence is worked out by a manager with an annual salary whose sole business it is to go to prison on behalf of the incriminated society. He has a certain sum of money allotted to him during his time in prison and leads a comfortable existence which many poor people envy. When adulterators are not found guilty by the court it is generally on account of political influences, for the milkmen take care, with a view to protection, to act as electoral agents. Finally, the courts take no notice of frauds which are not exceedingly serious, and when, as a rule, the amount of adulteration is not quite double that which is allowed by the law. "Fraud" consists in the addition of water and in the existence of less than 38 grammes of fat to the litre; but the court, as a rule, takes no notice of any deficiency of fat until there is less fat than 20 to 25 grammes a litre, so that when the Municipal Laboratory says that any milk contains a deficiency of fat between 38 and 25 grammes per litre, its work is quite useless. The estimation of salts which used to be employed is quite insufficient, for the adulterators used to add not water but skimmed milk, and the estimation of fat itself is in no way a real check, for the adulterators took to adding margarine to the milk so as to bring up the proportion of fat. One paper, the *Echo de Paris*, has organised a competition with a view of discovering a simple apparatus by which any member of the public can test the milk supplied to him, for at present the Municipal Laboratory takes no less than 24 hours to report on a given sample. This competition is open up to May 15th to any French or foreign inventor and the prize of 5000 francs will be allotted by a jury of chemists, hygienists, and eminent medical men. The committee is already appointed and the president is Professor Brouardel.

Jan. 28th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *The Accident to Professor Virchow.*

PROFESSOR VIRCHOW'S condition, which immediately after his accident was reported to be quite satisfactory, is apparently now not so good as might be desired. According to the *Berliner Klinische Wochenschrift* the subcutaneous hæmorrhage is nearly absorbed and callus has begun to develop; the state of the circulation and respiration is also said to be normal, but the patient does not sleep well. The surgeons in attendance have recommended him to abstain from work of any kind and from receiving visitors.

### *Pharmaceutical Chemists and Sick Clubs.*

The conflict between the pharmacies and the united sick clubs of Berlin to which allusion has already been made in THE LANCET of May 18th, 1901, p. 1435, has not yet come to an end. The immediate cause of the dispute was a financial one, the clubs requiring a discount of 10 per cent. to be granted to them, but the real causes, as I have explained in the passage above referred to, are more deeply seated and depend on the somewhat obsolete laws relative to the pharmaceutical profession. Owing to the strong organisation of the pharmaceutical chemists it was generally believed that the boycott of the majority of pharmacies would be a failure. On the other hand, the organisation of the clubs and the *esprit de corps* of the working population to which the club members exclusively belong have been strong enough to maintain the boycott and even to extend it. For instance, the pharmacists some months ago discontinued the granting of credit to club members, so that they (the members) had to pay for their medicines at once. As the majority of the members were not always provided with sufficient ready money the pharmaceutical chemists hoped by this means to coerce the clubs, but the proprietors of the unlicensed drug-stores, who in this controversy hold the position of "tertius gaudens," Mr. Taylor The annual report showed that during 1901 there were 3039 in-patients admitted, of whom 2645 were discharged as improved and only 258 as being no better Dr R O G Bennet and Mr Arthur Shipton, the former of whom has had 43 years', and the latter 24 years', service on the honorary medical staff, have resigned and have been appointed honorary consultants The honorary medical staff has been increased by the election of Dr John Braithwaite, Mr T B Flint, Dr George Lorimer, and Mr Herbert Shipton The Earl of Derby and Mr Frank Drewry were unanimously elected respectively chairman and vice-chairman of the committee of management

NEW SMALL-POX HOSPITAL—At the meeting of the Plymouth (Devon) Rural District Council held on Jan 24th it was decided to erect a small pox hospital to contain 12 beds The structure is to be of corrugated iron and the estimated cost is about £1000

DR JOHN SHIVES was called to the Bar at the Middle Temple on Jan 27th

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS

### *The Shop Hours Question*

A BILL dealing with this subject framed on the lines of the report of the House of Lords Committee of last session, has been introduced in the House of Commons by Sir Charles Dilke. Instead of leaving the initiative to a two thirds majority of the shopkeepers, as was proposed by Lord Avebury's Bill, this measure simply confers on local authorities the power to fix hours of closing for each day of the week. Provision is, of course made for certain special classes of shops, such, for instance, as shops for the sale of drugs, and for public houses There is a clause which proposes to enact that no child under 14 years of age shall be employed in a shop and another that no person shall be employed in a shop for more than 60 hours including meal times, in any one week Several sanitary clauses appear in the Bill One of these says that every shop shall be provided with sufficient and suitable accommodation in the way of sanitary conveniences, having regard to the number and sex of the persons employed

### *Proposed Amendment of the Vaccination Acts*

Mr BROADHURST one of the Members for Leicester, has introduced a Bill to amend the Vaccination Acts

### *The Midwives Bill*

Mr GRIFFITH BOSCAWEN has given notice that when the second reading of the Midwives Bill is moved he will move the rejection of the measure Since the introduction of this Bill many petitions in its favour have been presented in the House of Commons

### *Laundries and Factory Legislation*

When the Factory and Workshop Bill of last session was presented to Parliament by the Government it contained a clause bringing laundries within the scope of this class of legislation Objection, however, was taken to the proposed treatment of conventual institutions and rather than risk the passage of the measure the Government withdrew the whole clause Mr RITCHIE intimating that in another session he would endeavour again to deal with the subject Questioned on the matter at a recent sitting of the House of Lords the Prime Minister said that he hoped that the Government might find an opportunity for legislation during the present session, but he gave nothing in the nature of a definite pledge

### *The Case of Dr Rendall of Great Yarmouth*

On Monday, Feb 3rd, the Home Secretary will be asked by Dr Macnamara whether his attention has been called to the case before the General Medical Council of Dr R Rendall of Great Yarmouth, and whether he will take the opinion of the Law Officers of the Crown as to the legality of the proceedings

## HOUSE OF COMMONS

### THURSDAY JAN 23RD.

### *The Supply of Lymph.*

Mr BARTLEY asked the President of the Local Government Board whether private medical practitioners were now able to purchase Government lymph for those who were prepared to pay for vaccination or whether they had to obtain it as they could, chiefly from abroad—Mr LONG replied: The statutory duty of the Local Government Board as regards the supply of glycerinated calf lymph is limited to supplying it to public vaccinators for purposes of primary vaccination only, and their lymph establishment was formed with this object Arrangements were, however made to extend the supply so as to enable lymph to be provided for use by these officers in revaccinations and a very large amount has been supplied for this purpose. The organisation of the establishment is not such as would enable me to furnish lymph to private medical practitioners.—Mr BARTLEY: May I ask the right hon gentleman whether, in view of the present state of things, this lymph could not be supplied to private practitioners all over the country so that there might be a guarantee that the lymph used is really efficient?—Mr LONG: It would be a very serious thing to suggest that lymph should be supplied gratis—Mr BARTLEY: I did not mean gratis—Mr. LONG: Well or sold to private practitioners There is, however, no necessity for it, because I have ascertained that there is ample glycerinated lymph to be obtained outside that which is supplied by the Local Government Board—Mr BARTLEY Is it the fact that it nearly all comes from abroad?—Mr LONG Some of it no doubt, comes from Paris, but there are other sources of supply and I have no doubt that there is an abundant supply to be obtained in the market at the present time—Mr AMBROSE: Is it not the case that much of this lymph is inefficient?—Mr LONG: I do not think that that can be said. I have reason to believe that it is most efficient Perhaps the Local Government Board lymph is stronger, but I do not think that the other lymph is less efficient

### *The Small pox Epidemic*

Mr BARTLEY asked the President of the Local Government Board whether he could state what progress had been made, especially in London, in vaccination and revaccination during the present epidemic of small pox—Mr LONG replied I am not at present in a position to give any estimate of the extra number of vaccinations and revaccinations performed during the present epidemic. The returns as to the vaccination of infants born in 1901 and as to revaccinations by public vaccinators will be received in due course but there is no record of revaccinations performed by private medical practitioners I have, however, reason to believe that there have been a very large number of vaccinations in the last few months in London and the neighbourhood Since the beginning of September I have caused lymph to be issued to public vaccinators for 480 000 vaccinations—that is, about [illegible]00 000 in excess of the normal supply for this period A very considerable portion of the excess has been issued to the metropolis

### *Lead-Poisoning*

Mr COGHILL asked the Home Secretary (1) whether he was aware that, on Dec 19th a coroner's jury found that Alfred Jagger, of No 4, Back Williamson Buildings, Dewsbury road, Leeds, a painter's labourer, died from the effects of lead poisoning, and (2) whether, in view of the cases of lead poisoning occurring amongst house painters, he proposed this session to introduce any special legislation for their prevention—Mr RITCHIE replied that the facts were as stated in the first paragraph of the question, but the man was not a house painter as his hon friend would seem to imply He was one of the workmen employed by a firm of manufacturers who were now, at the suggestion of the factory inspector, introducing improvements in their works As regards the second paragraph he was of the same opinion as on March 5th last, when he said that he did not see his way to introducing the legislation suggested

### FRIDAY, JAN 24TH

### *Treatment of an Irish Harvester*

Mr. T M HEALY asked the Home Secretary if his attention had been called to the verdict of the coroner's jury in Dublin on Nov. 20th, in the case of a man named Moore who returning from England to his home near Castlebar was removed in a dying condition to Jervis street Hospital, Dublin on the arrival of the boat from Holyhead, whether he was aware that the guard Mr Keogh, swore that Moore was examined at Holyhead station by a doctor and refused admission to the Holyhead Hospital and was brought across in the *Cambria*, whether he would ascertain who was responsible for refusing this man admission to Holyhead Hospital and compelling him while dangerously ill to undertake a rough sea journey, and whether he could state whether this hospital was a voluntary or a rate aided institution—Mr RITCHIE replied I am not aware of the verdict referred to or of the evidence given at the inquest but from inquiries which I have made I find that Moore who was one of about [illegible]00 harvesters who arrived at Holyhead on the same morning, was not refused admission to the Holyhead Hospital That hospital is supported by voluntary contributions If Moore had been taken there I am informed that he would have been admitted As regards the sea journey, I understand that after remaining at the station and being attended by two medical men Moore, under medical advice, resumed his journey in the afternoon a telegram being sent to Dublin for an ambulance to be ready on his arrival

### *The Supply of Lymph*

Another question on the subject of the supply of lymph was addressed to Mr LONG at this sitting and the right hon gentleman repeated his reply that the organisation of the establishment of the Local Government Board was not such as to enable the department to supply lymph to private medical practitioners—Mr BARTLEY asked whether it was not possible to enlarge the establishment—Mr LONG replied that it had been very nearly doubled within the last few weeks and it was impossible at present to supply all the lymph required for primary vaccinations To supply private medical practitioners would task the resources of the establishment beyond its powers. They were doing everything that they possibly could, but if they could add to the supply they would do so

### *Researches on Cancer.*

Mr ARTHUR LEE asked the First Lord of the Treasury whether he would consider the desirability of advising the appointment of a royal commission on cancer on similar lines to that which had been appointed to inquire into tuberculosis—Dr FARQUHARSON asked the First Lord of the Treasury whether his attention had been directed to a scheme backed by the leaders of the medical profession for organised research in cancer and whether he would wait till this was formulated before committing himself to the costly and dilatory process of a royal commission.—Mr BALFOUR replied: In answer to the last question I have to say that my attention has been called to the passage in a newspaper to which the hon member refers I have no other information as to the progress which this interesting experiment in organisation is making. I am sure I wish it all success. As regards the other question I entirely agree with my hon friend as to the great importance of this subject of medical investigation, but I confess that my instinct is not in favour of attempting to deal with it by means of a royal commission I do not think that the cases of cancer and tuberculosis are at all parallel I will not develop my reasons for holding that opinion but I think that there is no parallel and I also think that the number of great scientific discoveries which have been made by royal commissions has been very limited, and that it would probably be better to leave this subject in the hands of the medical profession in all countries whose attention is, and has been for some of Pathology to Pauperism and Crime," and "Sane or Insane"; and in the *Medical Times and Gazette* he published papers on "Hedonism" and "Cerebral and Ganglionic Disorders of Mentation." He also did much good work with the microscope, his contributions being published in the Transactions of the Royal Microscopical Society. In 1872 he published a little book on invalid cookery which was favourably reviewed in THE LANCET of Sept 28th, 1872, p. 450.

He held advanced views on sanitation and on the compulsory notification and isolation of infectious diseases. When arguing in favour of treating habitual drunkards as lunatics he uses these forcible words: "The one great obstacle to the consideration of this subject may be said to be that bugbear of society known under the misnomer 'the liberty of the subject.' In what does it consist? Liberty to rob your neighbour's pocket by poor-rates; to destroy your family's peace of mind by eccentricity; to injure the public health by engendering syphilis. scrofula, rickets, and consumption; to cultivate epidemic disease in filthy and inhuman hovels; and to shorten the lives of the State's tax-producing subjects by dirt, drink, and debauchery."

Metcalfe Johnson was one of the old school—a gentleman by birth, by education, by instincts, always courteous, always kindly, and of conspicuous honesty and purity of purpose and life.

### JOHN MANLEY, J.P., M.R.C.S. ENG., L.S.A.

ON Jan. 21st, after a cerebral seizure, Mr. John Manley died peacefully at his home, the Highfields, West Bromwich, in the seventy-seventh year of his age. Mr. Manley was an active member of the social and municipal life of the town in which he lived and by his strong personality and force of character he exercised an influence upon all with whom he was associated. Born at Tortola in the West Indies, the son of a Wesleyan missionary, on the death of his parents he was brought to England to be educated for the medical profession. He became a Licentiate of the Apothecaries' Society in 1853 and a Member of the Royal College of Surgeons of England in 1864, and entered into partnership with Dr. Abercrombie at West Bromwich, shortly afterwards acquiring the practice. Destined to figure prominently in public matters he commenced by becoming a member of the old Board of Commissioners, an office which he resigned to become medical officer of health. This position he filled with tact and vigour for a term of 17 years. As one of the founders of the Free Library he displayed a keen interest in the duties connected with that institution, at the time of his death being chairman of the committee. He was also one of the council of the Queen's College, and one of the representative governors of the University of Birmingham. Public life had as many attractions for him as professional prominence, although he was President of the Midland Medical Society and a member of the board of management of the district hospital. He was made a Justice of the Peace for the borough, his decisions and opinions being highly valued and respected. Mr. Manley married a daughter of the Rev. Benjamin Wood, who died in 1888, leaving one son, Dr. J. H. H. Manley, the present medical officer of health of West Bromwich. At Mr. Manley's request his remains were cremated at Manchester and the ashes interred in his wife's grave at West Bromwich Cemetery. As a man of wide culture and one who had strong convictions on matters of varied interests Mr. Manley will be long remembered and his memory regarded with esteem.

---

UNIVERSITY OF CAMBRIDGE.—Mr. W. E. Johnson, M.A., of King's College, has been appointed the first Sidgwick Lecturer in Moral Science under the new foundation in memory of the late Knightbridge Professor.—The Balfour Studentship, value £200 a year, in Animal Morphology, will be vacant at the end of the present term. Candidates are to apply to Mr. J W. Clark, secretary to the managers, not later than Feb 28th.—In recognition of his services to the University the degree of M.A. *honoris causâ* has been conferred on Dr. Walter Ernest Dixon, Assistant to the Downing Professor of Medicine.—Dr. A. Hill, Master of Downing College, has been appointed by the Council of the Senate a representative member of Girton College; and Dr. W. H. R. Rivers, of St. John's College, an additional member of the Special Board for Moral Science.

## Medical News.

VACCINATION EXEMPTION CERTIFICATES.—At the Exeter Police-court on Jan. 23rd two applications for vaccination exemption certificates were refused.

THE Council of King's College, London, have elected the Rev. T. B. J. Parker, M.A., Worcester College, Oxford, and formerly Canon of Rockhampton, Queensland, to the office of Chaplain of King's College Hospital.

THE BRITISH MEDICAL BENEVOLENT FUND.—In accordance with the will of the late Mr. Robert Webb Watkins, F.R C.S. Eng., of Towcester, his executors have paid a legacy of £100, duty free, to the British Medical Benevolent Fund.

THE SEWAGE OF TROWBRIDGE.—The Local Government inspector (Mr. R. H. Bicknell) held an inquiry on Jan. 24th into the application of the Trowbridge (Wiltshire) Urban District Council to borrow £35,960 for the purposes of sewage and sewage disposal.

AT the meeting of the Okehampton Borough Council held on Jan. 23rd it was reported that the Charity Commissioners would favourably consider an application for permission to apply the income of £80 per annum, derived from non-ecclesiastical charities, for the maintenance of a cottage hospital, provided that there was a prospect of a hospital being founded on a sound basis. The council decided to take steps to secure a suitable site for the proposed hospital.

THE seventh annual dinner of the Mirfield and District Medico-Chirurgical Society was held at the Masonic Hall, Mirfield, on Jan. 31st, Dr. John Stewart, the President, being in the chair. Covers were laid for 42. Amongst those present were Professor W. Japp Sinclair, Mr. B. G. A. Moynihan, Dr. E. O. Croft, Dr. A. Bronner, Mr. T. B. Fairclough, Dr. A. Anderson, Mr. T. W. Sproulle, Dr. L. J. Milne (honorary secretary), Dr. W. Brander, Mr. C. Clay, Mr. C. A. Mitchell, Mr. T. Oates Halliwell, Mr. P. MacGregor, Mr. G. W. K. Crosland, Mr. Bruzaud, Dr. T. A. Green, Mr. J. A. Erskine Stuart, Dr. N. H. Pike, Mr. R. H. Shaw, Dr. G. de J. Patterson, Mr. A. T. Griffiths, Mr. W. Shaw, Mr. G. D. Crowther, and Dr. J. F. Hodgson. The dinner was preceded by an address by Professor Sinclair on "Early Abortion in General Medical Practice." The next meeting will be held at Dewsbury Infirmary on Feb. 12th at 8.30 P.M.

RECEPTION AT THE BOVRIL FACTORIES.—In response to the invitation of the Bovril Company a very considerable number of medical men attended an inspection of the company's new factories on Jan. 23rd. The visitors were received by Viscount Duncannon, the chairman. The many processes concerned in the production of bovril were watched each in its own department with great interest. Demonstrations were also given of the way in which the albumin and the fibrin of the meat are retained in the extract. Not the least interesting section of the demonstration was that relating to the production of various rations and specialities supplied by the Bovril Company to the army, to the navy, and to exploring expeditions. Some interesting statistics were supplied bearing upon the enormous quantity of extract made and the amount of meat required. The machinery for the purpose is of an ingenious description and is specially designed in order that bovril may not be touched by the hand at any stage in the manufacture. The new premises are well lighted, well ventilated, and commodious. A large space on the roof is reserved for the employés for recreation purposes.

DEVONSHIRE HOSPITAL, BUXTON.—The annual meeting of the committee of management of the Devonshire Hospital, Buxton, Derbyshire, was held at the hospital on Jan. 11th, the Duke of Devonshire presiding. Before the ordinary business of the meeting commenced the Duke of Devonshire, speaking in the name of the committee, presented Mr. Joseph Taylor, the late secretary of the hospital, with a silver inkstand. Mr. Taylor, who had filled the office of secretary for 36 years and had in this capacity rendered most important services to the institution, was then elected a member of the committee of management. At a later stage of the business Mr. William Stevenson was elected secretary in succession to

**County Asylum**, Chester.—Third Assistant Medical Officer, unmarried. Salary £160 per annum, with board, lodging, and washing.

**County Asylum**, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200, with apartments, board, attendance, and washing.

**District Infirmary**, Ashton-under-Lyne.—House Surgeon. Salary £120 a year and board and lodging.

**Durham County Asylum.**—Junior Assistant Medical Officer. Salary £140, rising to £160, with board, laundry, and attendance.

**Easington Union and Rural District Council**, Castle Eden, Durham.—Medical Officer, &c. Salary £150 per annum.

**Essex and Colchester Hospital**, Colchester.—Assistant House Surgeon (unmarried). Salary at rate of £50 per annum, with board, lodging, and washing

**Fisherton Asylum**, Salisbury.—Assistant Medical Officer. Salary £150 per annum, with board lodging, and washing

**General Hospital**, Wolverhampton.—Assistant House Physician, also Assistant House Surgeon, both for six months, with honorarium at rate of £75 per annum, and board, lodging, and washing.

**Hastings, St. Leonards, and East Sussex Hospital.**—House Surgeon, unmarried. Salary £75 per annum, with residence, board, and washing.

**Kent County Asylum**, Barming Heath, Maidstone.—Fourth Assistant Medical Officer and Pathologist, unmarried. Salary £175 per annum, rising to £200, with quarters attendance, &c.

**Kent and Canterbury Hospital.**—House Surgeon, unmarried. Salary £100 a year, with board and lodging.

**Lancashire County Asylum** Winwick, Newton le-Willows.—Assistant Medical Officer, unmarried Salary £150 per annum, rising to £200, with apartments, board, attendance, and washing.

**Lincoln County Hospital.**—Junior Male House Surgeon for six months, eligible for re-election Honorarium of £25 for each period of six months, with board, residence, and washing.

**New Sanatorium for Phthisical Patients of the Poorer Classes**, Blue Mountains, New South Wales.—Resident Medical Officer, unmarried. Salary £300 per annum, with board and residence.

**North Staffordshire Infirmary and Eye Hospital**, Hartshill, Stoke-upon-Trent.—Assistant House Surgeon for six months. Board, apartments, and washing, and at least £25 as honorarium.

**Paddington Green Children's Hospital**, London, W.—Surgeon to the *Throat and Ear Department.*

**Poplar Hospital for Accidents**, Poplar, E.—Resident House Surgeon. Salary £135 per annum, with board and residence.

**Queen Adelaide's Dispensary**, Pollard row, Bethnal Green-road, E.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, coal, gas, and attendance.

**Radcliffe Infirmary**, Oxford.—House Physician for six months. Salary at rate of £80 per annum, with board and lodging.

**Royal Dental Hospital of London**, Leicester-square.—Lecturer on Materia Medica in Relation to Dental Surgery.

**Royal Halifax Infirmary.**—House Surgeon, unmarried. Salary £120 *per annum, with residence, board, and washing.*

**Royal Hospital for Diseases of the Chest**, City-road, E C.—House Physician for six months. Salary at rate of £60 per annum, with apartments, board, and washing.

**Royal National Hospital for Consumption and Diseases of the Chest**, Ventnor.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging.

**Royal Southern Hospital**, Liverpool.—Junior House Surgeon. Salary 63 guineas per annum.

**St. George's Retreat**, Burgess-hill, Sussex.—Resident Assistant.

**Seamen's Hospital Society** (Branch Hospital, Royal Victoria and *Albert Docks, E*).—House Surgeon Salary £50 per annum, with board and residence.

**Suffolk County Asylum.**—Second Assistant Medical Officer. Salary £130 per annum, rising to £150, with board, lodging, laundry, and attendance.

**Victoria Children's Hospital**, Park-street, Hull.—Lady House Surgeon. Salary £50 per annum, with board and laundry. Also a Lady Assistant House Surgeon Salary £40 per annum, with board and laundry

**West Bromwich District Hospital.**—Resident Junior House Surgeon. Salary £50 per annum, with board, lodging, washing, and attendance.

# Births, Marriages, and Deaths.

## BIRTHS.

**Anderson.**—On Jan. 25th, at Faversham, Kent, the wife of Charles Macdonell Anderson, M.D. Edin., of a daughter.

**Copeman.**—On Jan. 21st, at the Parade, Cowes, I.W., *the wife of* Alfred Heathcote Copeman, M A., M.D. Dub., M.R.C.S., L.R.C.P. Lond., of a daughter.

## MARRIAGES.

**Bidwell—Fichardt.**—On Jan 2nd, at the Cathedral, Bloemfontein, South Africa, Charles Hugh Bidwell, M.R.C.S., L.R.C.P. Lond., to Maude Geraldine, daughter of the late G. A. Fichardt.

**Davies—Scott.**—On Jan. 22nd at the Church of St. Michael, Teignmouth, S Devon, S H Battray Davies, M.R.C.S., L.R.C.P. Lond., to Mary Douglas, daughter of Lieutenant Colonel Scott.

## DEATHS.

**Nelson.**—On Dec. 25th, at 15, Bootham terrace, York, George Dawson Nelson, M.D., M.R.C.S.E., L.S.A. formerly of Bridlington Quay, aged 79 years

**Stockton.**—On Jan. 25th, at King's Sutton, near Banbury, Arnold Stockton, M.R.C.S., L.R.C.P. Lond., aged 29.

**Weir.**—On Jan. 25th, at Guy's Hospital, from an accident, Arthur Nesham Weir, F.R.C.S., aged 32.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## SCARLET FEVER AT A LAUNDRY.

Non compliance with isolation laws at any time, and more so just now when the greatest precautions are being taken to prevent the spread of small-pox and other diseases, is an infringement of the Public Health Act deserving severe punishment. A case in point came before the Hailsham Petty Sessions on Jan. 22nd, when a man was summoned at the instance of His Majesty's inspector of factories for "unlawfully causing or allowing wearing apparel *to be cleaned in a dwelling house occupied by him* while inmates of the said dwelling house were suffering from scarlet fever, contrary to the Public Health Act." The defendant lived at Willingdon, where he carried on an extensive laundry business. His clients were almost solely residents in the neighbouring town of Eastbourne On Nov. 23rd, 1901, Mr. A Wheeler Taylor was called in from Eastbourne to see the children of the defendant, and on the following day he diagnosed them to be suffering from scarlet fever. His advice to have the patients removed *to the sanatorium* was not complied with. *They were allowed* to remain on the premises, and it was only in the first week of this year that a certificate was given that the children were free from infection. From Nov. 23rd onwards the laundry business was carried on as usual in a room adjoining the dwelling-house, but connected with it. There was the daily arrival of soiled linen and the daily exit of clean clothes. On Dec. 5th the premises were visited by Mr. Hugh Stott in his capacity as medical officer of health of East Sussex and as the medical officer of the Eastbourne rural district. The process of washing was being continued, clothes were being brought in and being sent home, and at the same time he found the children on the premises suffering from scarlet fever. The defendant told Mr. Stott that he would rather have his work stopped than remove his children to the isolation hospital at Polegate. But neither course was taken. Six days later—on Dec. 11th—a sanitary inspector saw the defendant who was about to deliver laundry work in Eastbourne. The defendant was not allowed to accomplish his errand until the "washing" had been disinfected at Polegate. An epidemic of scarlet fever might easily have been conveyed to Eastbourne by the ignorance and stupidity of the laundry proprietor. In the case of scarlet fever, although only in a mild form, isolation is the most effectual means of arresting its spread, and the general community have a right to be protected from the acts of such a person as the defendant. The case was an aggravated one, and the defendant, who had rendered himself liable to a fine of £10, was mulcted in a penalty of £2 2*s*., inclusive of costs.

## PUBLIC VACCINATORS AND PRIVATE FEES.

*To the Editors of* THE LANCET.

Sirs,—I inclose a cutting from the *Nottingham Guardian* re-vaccination. You will see that Mr. J. Jeffares, who is public vaccinator for that district, has got a free advertisement at the hands of the Shardlow Guardians. It is stated that he vaccinates people privately for 2*s*. 6*d*., whereas his official pay is 6*s*. This appears to me to be touting for vaccination cases at 2*s*. 6*d*. Also what will the authorities say when they give him 6*s*. for a case done as a public vaccinator, and find that he announces that he can do private patients equally as well at 2*s*. 6*d* ?

Thinking this may be of interest to readers of THE LANCET who are public vaccinators.

I am, Sirs, yours truly,

Jan. 14th, 1902. 1902.

*** We do not read the paragraph in the *Nottingham Guardian* as our correspondent reads it, but we think it wrong for a public vaccinator to forego his lawful fees because his action may embarrass his brother officials.—Ed. L.

## CORONERS' INQUESTS.

A correspondent informs us that recently he received the following letter from the coroner for his district:—

> "Dear Dr. ——,—Will you kindly in future as soon as possible notify to me all sudden deaths similar to the Revd. ——, in order to save trouble to the relatives by so doing you oblige,
>
> "Faithfully yours,
>
> "—— ——."

Our correspondent adds "The case in point was that of an old gentleman, aged 74 years, who died in five hours from apoplexy. I was his regular attendant had been attending him up to his death, and was with him during his last illness. The coroner himself with a policeman marched up to the house and, naturally, disturbed the family. Is there any authority for this order? the coroner is a medical man in practice in the city." Presuming that our correspondent gave the usual medical certificate of the cause of death, as doubtless he did, we think it to have been unnecessary, to say the least, for the coroner and his attendant policeman to go to the residence of the deceased. As for the coroner's request that he years past, directed towards it. Of course, if those competent to speak for the medical profession take a different view--they are more qualified to judge than I am and if their views are brought before the Government they will receive full consideration.—Mr. LEE: Will the right hon. gentleman consider the advisability of recommending a substantial grant of money for this inquiry in view of the fact that there is no fund available for the purpose?—Mr. BALFOUR: The question which my hon. friend now asks raises a very large issue and I should not like to touch upon it at the present time. The amount of Government money given in this country for experiments is not very large, but whether it should be or should not be increased is a question which I cannot answer on the spur of the moment, it requires very careful consideration and consultation with my colleagues. I may add that there has been no application up to the present time for a grant in order to carry out this particular object.

## MONDAY, JAN. 27TH.

### *The Sources of Vaccine Lymph.*

Mr. CORRIE GRANT asked the President of the Local Government Board (1) whether he could state the original sources of the vaccine lymph supplied by the Government; (2) whether any was derived from the inoculation of small-pox on animals; (3) whether a pure culture of the organism of vaccinia could be supplied in place of lymph; (4) whether the strength of the virus could be standardised so as to measure the dose administered; (5) whether the Government guaranteed the purity and innocuity of the lymph they supplied; and (6) whether the Government would take steps to secure the control and supervision of all lymph used in this country.—Mr. LONG replied: The lymph supplied by the Government is derived from calves which have been vaccinated with lymph from other calves and is not obtained by inoculating animals with small-pox. The reply to the third and fourth questions is in the negative. The Government give no guarantee, but they use every effort to secure that their lymph shall be free from undesirable organisms. As at present advised I do not propose to ask for power to control the lymph supplied from other sources.

### *The Small-pox Epidemic*

Mr. JOSEPH A. PEASE asked the President of the Local Government Board whether he was aware that several cases of small-pox had been traced to an outbreak on the s.s. *Anglian* from Boston, docked in the Royal Albert Dock on Jan. 3rd last; whether the port sanitary authority thoroughly inspected the s.s. *Anglian*, and why the existence of small-pox on board was not discovered at once and notified, seeing that the dockers were engaged for two or three days dealing with the cargo before the disease was notified; and whether, with a view to prevent similar outbreaks, steps had been taken to insure that vessels arriving with disease on board should be placed in quarantine until a clean bill of health had been certified for by the port sanitary authority.—Mr. LONG replied: I am aware of the facts referred to the first paragraph of the question. I am informed that on the arrival of the vessel at Gravesend the captain reported "all well" and "no sickness during the voyage." As the ship did not come from an infected port the persons on board were not medically examined and the vessel proceeded to dock where the cattlemen, after the cattle had been discharged, cleared from the ship. On the following day one of the cattlemen, feeling ill, presented himself at the Branch Seamen's Hospital where he was seen to be suffering from small-pox and he was conveyed to hospital. The port medical officer traced nearly all the persons who had left the ship, and in all five cases of small-pox have been dealt with. Vaccination was performed in the case of all persons on board willing to be vaccinated. The vessel has been disinfected and the names and addresses of the persons on board have been notified to the medical officers of health of the districts concerned. The system of quarantine is not in force in this country. The method adopted consists of medical inspection of ships coming from infected places or having illness on board, isolation of infected persons, and keeping under observation those brought into contact with them. The medical officer of the Port of London has taken steps to have all vessels from Boston and New York, where it is stated that small-pox is prevalent, medically inspected on arrival at Gravesend.

## TUESDAY, JAN. 28TH.

### *The Royal Army Medical Corps.*

Dr. FARQUHARSON asked the Secretary of State for War whether he could inform the House when the last examination took place for commissions in the Royal Army Medical Corps, how many vacancies there were, and how many candidates competed for them; and whether, to encourage the flow of candidates from the medical schools, he would quickly produce the Royal Warrant founded on the recommendation of his committee?—Mr. BRODRICK replied: The last examination was in February, 1901, when 22 appointments were offered and 10 candidates competed. The Royal Warrant will shortly be published.

### *Sanitation in Glasgow.*

Mr. THOMAS BAYLEY asked the Lord Advocate, as representing the Secretary for Scotland, whether his attention had been called to the fact that the provisions of the Glasgow Building Regulation Act, 1890, whereby it was enacted that all houses must be supplied with proper water sanitary accommodation, had not been carried out; could he state what steps the Corporation of Glasgow were taking to carry out this Act; and if, in the event of the corporation failing to carry out their own building regulation act, would the Government take any proceedings to insist on their so doing.—The LORD ADVOCATE replied: The statute to which the hon. Member intends to refer is the Glasgow Police Amendment Act, 1890. Since it came into operation a great deal has been done at the instance of the Corporation of Glasgow to carry its provisions into effect. Further measures designed to secure so far as possible the desired result have been receiving the attention of the Local Government Board for Scotland and of the Glasgow corporation which has assured the Secretary for Scotland that the matter is receiving its earnest consideration. The last paragraph of the hon. member's question suggests an hypothesis and I am not prepared to pledge the Local Government Board in circumstances which have not yet arisen.

# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ARMSTRONG, HUGH, F.R.C.S. Eng., has been appointed Medical Officer of the Friendly Societies' Medical Institute, Tamworth, New South Wales.

BELL, R. H., M.A., M.B., M.C. Cantab., has been appointed Obstetric Tutor and Registrar to St. Thomas's Hospital, vice Mr. Fairbairn.

BROWNE, T. W. S., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Acts for the Chatham District.

CHOLMELEY, W. F., F.R.C.S., has been appointed Honorary Assistant Surgeon to the Wolverhampton General Hospital.

COLLINS, PATRICK JOHN, L.K.Q.C.P. Irel., L.R.C.S. Irel., of Woolabra, New South Wales, has been appointed a Justice of the Peace.

DICKMAN, H. G., M.B., M.S. Edin., has been appointed Medical Officer of Health for the Urban District of Diss, Norfolk.

EDWARDS, G. M., M.B., B.S. Cantab., has been appointed Certifying Surgeon under the Factory Acts for the Harrow District of Middlesex.

ELLIOT, S., M D. Edin., has been appointed Certifying Surgeon under the Factory Acts for the West District of Caithness.

FAIRBAIRN, J. S., M.B Oxon., F.R.C.S. Eng., M.R.C.P. Lond., has been appointed Assistant Obstetric Physician to St. Thomas's Hospital in the room of Dr. Walter Tate.

FISHER, CHARLES, M.B., B.S. Durh., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician to the City of London Hospital for Diseases of the Chest, Victoria-park, London.

FLETCHER, J. H., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Ince Urban District Council.

GRAHAM, A. W., M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the District of Beaconsfield and Dalrymple, Tasmania.

HAMILTON, J. A. G., M.B., L.M. Dubl., has been appointed Gynæcologist at the Adelaide Hospital, South Australia.

HARRIS, A. B., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for the Loughton Urban District.

HEMSTED, R. H., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Factory Surgeon for the Rural Districts of Whitchurch and Kingsclere, Hants.

HOPE, J. W., F.R.C.P. Edin., has been appointed Honorary Consultant to the Fremantle Public Hospital, Western Australia.

HURST, J. D., M.M. Melb., has been appointed Public Vaccinator at Laverton, Western Australia.

MACLENNAN, ALEX., M.B. and C.M., has been appointed an Extra Honorary Surgeon to the Royal Hospital for Sick Children.

MOFFIT, J. E. J., L.K.Q.C.P., L.R.C.S. Irel., has been appointed Government Medical Officer and Vaccinator for Balranald.

PALMER, ARTHUR A., M.B., M.S. Edin., has been appointed a Member of the Administrative Board of the Civil Ambulance and Transport Brigade, New South Wales.

PENFOLD, THOMAS C., M.B., M.S. Edin., has been appointed Medical Officer of Health for the Hexham Rural District.

ROBB, W., M.B., M.S. Glasg., has been appointed Medical Officer of Health for the Irthlingborough Urban District.

SAYER, THOMAS, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Resident Medical Officer at the Leeds Sanatorium for Consumption at Gateforth.

SCOTT, F S., M.B., B.Ch., B.A.O. R.U.I., has been appointed Medical Officer to attend to the destitute poor and aborigines at Mitcham, South Australia.

SHAW, F. C. S., J.P., M.B. Syd., has been made an Appointed Member of the Licensing Court for the Licensing District of Emmaville, New South Wales.

SPROTT, GREGORY, M.B. Glasg., D.P.H., has been appointed an Honorary Medical Officer of the Hobart Hospital, Tasmania.

SPROULE, W., M.D. Edin., has been appointed Medical Officer at the Hospital, Wyalong, New South Wales.

STANLEY, G. P., M.B., Ch.M. Syd., has been appointed Medical Officer to the Friendly Societies' Medical Institute, Tamworth, New South Wales.

WOLFHAGEN, JOHN EDGAR, M.B., Ch.M. Edin., has been appointed a Member of the Court of Medical Examiners, Hobart, Tasmania.

# Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

ANCOATS HOSPITAL, Manchester.—Resident House Surgeon. Salary £100 per annum, with board, &c.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Surgical Officer. Salary £60 per annum, with board, washing, and attendance.

BOLTON INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £80 per annum, with apartments, board, and attendance.

BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, single. Salary £100 per annum, with board and residence.

BRECON INFIRMARY.—Resident House Surgeon, unmarried. Salary £100 per annum, with apartments, board, attendance, fire, and gas.

BRISTOL EYE HOSPITAL.—House Surgeon. Salary £80, with residence and maintenance.

BRISTOL GENERAL HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, &c.

CAITHNESS COUNTY COUNCIL.—Medical Officer of Health. Salary £250 and £50 for travelling and other expenses.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY** (3rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. F. Payne: Clinique. (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Surgical Emergencies.

ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.

**TUESDAY** (4th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. Ewart: Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Robinson: Uterine Hæmorrhage.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Dr. A. Macfadyen: The Cell, its means of Offence and Defence. Immunity.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Ferrier: Varieties of Gait

**WEDNESDAY** (5th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. A. H. Tubby: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. McAdam Eccles: Lantern Demonstration on Hernia.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—8 P.M. *Dr. D. Grant: The Examination and Diseases* of the Accessory Sinuses of the Nose.

**THURSDAY** (6th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W C.).—4 P M. Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Davis: Medical Anatomy and Physical Diagnosis.

CHARING-CROSS HOSPITAL.—4 P M. Dr. Abercrombie: Demonstration of Medical Cases. (Post-Graduate Course.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Colman: Demonstration of Selected Cases.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION (11, Chandos-street, Cavendish-square, W.).—4 P.M. General Meeting. Discussion on the Ventilation of School Buildings, with special reference to its application to existing buildings, opened by Mr. W. N. Shaw. Special appliances connected with ventilation will be exhibited.

**FRIDAY** (7th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. E. Clarke: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Surgical Emergencies.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. E. Ray Lankester: The New Mammal from Central Africa and other Giraffe-like Animals.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. J. Taylor: Epilepsy.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. II of 1901, which was completed with the issue of Dec. 28th and the Title-page to the Volume, were given in THE LANCET of Jan 4th.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with *none of whom have the Proprietors any connexion whatever*) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... ... | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

## METEOROLOGICAL READINGS.

*(Taken daily at 8.30 a.m. by Steward's Instruments.)*

*THE LANCET Office, Jan. 30th, 1902.*

During the week marked copies of the following newspapers have been received:—*Blackburn Gazette, Bournemouth Guardian, Dudley Herald, Northern Guardian, Lancashire Post, Bristol Times, Grantham Journal, Plymouth Morning News, Western Mercury, Yorkshire Post, Ipswich Times, Times of India, Pioneer Mail, Citizen, Architect, Builder, Blyth News, Devon and Exeter Express, Barnsley Express, Ulster Echo, Manchester Dispatch, Glasgow Citizen, Bradford Observer, Darlington Star, Sheffield Daily Telegraph, Municipal Reporter, Allgemeine Medicinische Central Zeitung, Revista Medica de San Paulo, Echo, Daily Mail, Daily Express, Yorkshire Post, Standard, Bristol Mercury, Windsor and Eton Express, Reading Mercury, La Caducée, Hong Kong Weekly Press, Herts Advertiser, Times of India, Pharmaceutical Journal, Aberdeen Free Press, Manchester Guardian, Dublin Evening Telegraph, Southampton Echo, Stafford Advertiser, Islington Gazette, Coventry Herald, Whitehall Review, Belfast News, Birmingham Daily Mail, Lancaster Guardian, &c.*

*future all such deaths should be notified to him*, he has a perfect right to ask that such procedure may be followed, but we do not think that he has any right to demand it in virtue of his office.

### MEDICAL PRACTITIONERS AND THE SALE OF POISONS.

*To the Editors of* THE LANCET.

SIRS,—In your annotation regarding Medical Practitioners and the Sale of Poisons in THE LANCET of Jan. 4th, p. 44, you fall into several errors. In the first place you say "the Act forbids a medical man or anyone else not registered under the Pharmacy Act to keep a shop or to supply scheduled poisons," &c. The Act of 1868 certainly did so; the first clause of the Act forbade anyone but a "pharmaceutical chemist or a chemist and druggist within the meaning of the Act" to do so. This, however, was repealed by the *Pharmacy Amendment Act* of 1869 which distinctly permitted medical practitioners to keep open shop and to sell scheduled poisons. The first clause of that Act reads:—

> "Nothing contained in the first 15 sections of the recited Act (1868) shall affect any person who has been registered as a legally qualified medical practitioner before the *passing of this Act*; and the said clauses shall *not* apply to any person who may hereafter be registered as a legally qualified practitioner, and who in order to obtain his diploma for such registration shall have passed an examination in pharmacy," &c.

Then it is not in virtue of Section 3 of the Amendment Act that a medical practitioner may sell or deliver medicines containing scheduled poisons to his patients: it is in virtue of Section 1, which I have just quoted. Section 17 of the Act of 1868 required all scheduled poisons to be labeled with the name of the poison, the word "poison," and the name and *address of* the seller, &c. The third section of the Amendment Act of 1869 which you quote is merely a regulation which makes it unnecessary to label a scheduled poison with the word "poison" when it is contained in a mixture dispensed to prescription. The Act of 1869 placed pharmaceutical chemists and registered medical practitioners on the same footing as regards keeping open shop and *the sale of scheduled poisons*, and they have *remained* so until the recent decision of the General Medical Council. Both have been in the habit of keeping unqualified assistants and apprentices. Should an unqualified assistant break the law by selling a scheduled poison he is fined, but in the case of a pharmaceutical chemist the punishment stops short with the assistant. But should the doctor's unqualified assistant break the law then the doctor must be also punished by worse than fine or imprisonment—he must have his means of livelihood taken from him. Surely a crime which merits so severe a punishment in the one case is deserving of some punishment in the other.

I am, Sirs, yours faithfully,

Jan. 11th, 1902. M.D.

*** We believe our view of the effect of the Pharmacy Acts to be correct, the matter being regulated by the sections upon which we laid stress as well as by that to which our correspondent refers. With regard to the question raised at the end of his letter, it was clearly the opinion of the General Medical Council that the medical practitioner should not employ others to break the law and then escape all responsibility in the event of their detection.—ED. L.

### TAP'S PATENT FUMIGATOR.

THE feature of this simple little apparatus is the way in which the supply of the disinfectant is regulated. The apparatus consists of a spirit lamp situated over which is a metal evaporator. Just above the evaporator is a cone-shaped container with its apex downwards. By means of a screw at the top of the container a metal rod moves up or down inside the apex of the hollow cone, so that the dropping of the disinfectant may be easily controlled. It is the same system as is employed in the stylographic pen, by which the flow of ink is regulated. Almost any kind of disinfectant fluid can be used in the apparatus, or anything in fact that is capable of being vapourised. The fumigator is supplied in a portable form by Messrs. S. Maw, Son, and Sons, 7 to 12, Aldersgate-street, London, E.C.

### IMMUNITY FROM SMALL-POX.

*To the Editors of* THE LANCET.

SIRS,—In reference to your annotation last week (p. 248), I had variola about 20 years since. I had been previously well vaccinated. I again unsuccessfully vaccinated myself on Jan. 13th.

I am, Sirs, yours faithfully,

Jan. 27th, 1902. SURGEON.

◆

*Campestres.*—A must make very sure of his ground before he does anything, for we suspect that he has been misinformed. But if he is certain, from trustworthy and undeniable evidence, that B has openly stated an intention of ousting him he is at liberty to cease to have professional or friendly relations with B. Medical men are constantly placed in positions of rivalry towards each other, but there is no reason why competition should not be conducted in an honourable manner.

*P.*—The eggs should be placed in the water glass on the day on which they are laid, and left there until they are required.

*M.A. Oxon.*—Many laboratory boys are asked to discharge more arduous and delicate scientific duties.

### OPERATIONS.

#### METROPOLITAN HOSPITALS.

**MONDAY** (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.) St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY** (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY** (5th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY** (6th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY** (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.). West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.).

**SATURDAY** (8th).—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.) Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

### SOCIETIES.

**MONDAY** (3rd).—SOCIETY OF ARTS.—8 P.M. Dr. S. Rideal: The Purification and Sterilisation of Water. (Cantor Lecture.)

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-square, W.).—4.30 P.M. Cases and Specimens will be shown by Mr. A. Cheatle, Mr. Lake, Mr. Lawrence, Dr. Macnaughton-Jones, Dr. Pegler, Dr. Tilley, Mr. Whitehead, Mr. Yearsley, Dr. Milligan, and Dr. J. Horne. Presidential Address: Prof. U. Pritchard.

**TUESDAY** (4th).—PATHOLOGICAL SOCIETY OF LONDON (King's College).—8 P.M. Laboratory Meeting. Dr. N. Dalton: Hyaline Fragmental Bodies in a Syphilitic Patch.—Dr. Whitfield: On Pappendium's Staining Method.—Dr. Howlett: The Absorption of Antitoxin by the Stomach and Rectum.—Dr. Daniels: Avian Filariæ from Guiana.—Mr. Cheatle: Healing of Aseptic Fractures.—Dr. Howlett (for Prof. Simpson): Preparations of Plague Bacilli from Man and Animals.

**WEDNESDAY** (5th).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Annual Meeting. Specimens will be shown by Dr. A. Routh, Dr. W. Duncan, Mr. Bland-Sutton and others. The President (Dr. Horrocks) will deliver the Annual Address.

**THURSDAY** (6th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Dr. W. Ewart: Scleroderma with Raynaud's Disease.—Dr. S. P. Phillips: Epistaxis in Rheumatism.

RONTGEN SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper;—Mr. E. W. H. Shenton: A System of Radiography.

NEUROLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8 30 P.M. Annual Meeting. Annual Address:—Mr. H. W. Page (President): Concussion of the Brain in some of its Surgical Aspects.

**FRIDAY** (7th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith-road, W.).—8.30 P.M. Discussion on the Treatment of Inoperable Cancer. Mr. A. Cooper, Mr. S. Boyd, Mr. Butlin, and Mr. H. Morris will speak.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8.45 P.M. Dr. R. E. Scholefield: Some Cases of Feigned or Functional Disease.

SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—8,30 P.M. Clinical Evening.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by Dr. L. Lack, Mr. R. Lake, Dr. F. W. Bennett, Mr. A. Thorne, Dr. L. H. Pegler, Mr. Waggett, Dr. H. J. Davis, and Dr. Donelan.

# A Clinical Lecture

ON

# TWO CASES OF SOLID ABDOMINAL TUMOUR WITH ASCITES.

*Delivered to the Post-Graduate Class at Charing Cross Hospital on Oct. 24th, 1901,*

BY THOMAS WATTS EDEN, M.D. EDIN., M.R.C.P. LOND.,
ASSISTANT OBSTETRIC PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—By the kindness of Dr. Mitchell Bruce and Dr. Amand Routh I show you two cases of abdominal tumour, calling attention to their points of similarity and contrast.

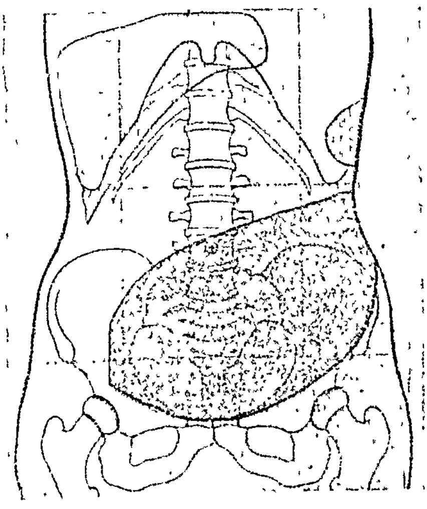
In the first case the patient, a married woman, aged 64 years, was admitted to Charing Cross Hospital under the care of Dr. J. Mitchell Bruce, on Oct. 15th, 1901, complaining of enlargement of the abdomen and of pain. Her past history presents few points of importance. She has had seven children, and menstruation ceased 15 years ago at the age of 49 years. For upwards of 10 years she lived in India, her husband being a soldier. Her family history reveals the presence of a marked tendency to tuberculosis, but she has herself been free from any trace of that disease. Indeed, she never remembers having been ill until Christmas, 1900, when she had an attack of rheumatism. After this she remained in good health until July, 1901, when she began to be troubled with pain in the abdomen which was felt at first below the left costal margin. She also had at this time some incontinence of urine and great frequency of micturition. Since that period her health has failed steadily; there has often been a little sickness in the morning, she has lost flesh, while the abdomen has increased in size, and her strength has also been failing. There has been no discharge, hæmorrhagic or other, from the vagina.

On admission it was noted that there was slight œdema of the legs and feet. The urine was found to be normal in all respects, and although repeatedly examined since her admission it has been always free from abnormal constituents. Both morning and evening temperatures are a little subnormal. The heart and lungs are sound. Inspection of the abdomen shows considerable distension of the lower abdomen which is slightly pendulous. The greatest girth is a little below the umbilicus and measures 45 inches. Above the umbilicus the abdomen is not appreciably distended. Percussion when the patient is in the dorsal position reveals an area of dulness the extent of which is indicated in the sketch. The whole of this area is not absolutely dull, the left lumbar region being sub-resonant. When the patient is turned upon her right side the right lumbar region remains resonant, while the percussion note in the left lumbar region becomes a little less impaired, but by no means clear. Palpation of the dull area shows that it contains a solid tumour freely moveable in a collection of fluid which surrounds it. A fluid thrill can be obtained from side to side passing in front of the tumour. "Dipping" is readily obtained over most of the dull area, while the solid tumour can be tossed from side to side or from below upwards like the fœtal head in a uterus over-distended with liquor amnii (external ballottement). The solid tumour is oval in shape with its long axis transverse to that of the body; its lower edge can be palpated just above the pubes, but the percussion dulness is continued to the pubes without a break. The surface of the tumour is nodular. There is very little abdominal tenderness. On vaginal examination some prolapse of the post-vaginal wall was found; the uterus was directed forwards and was very freely moveable in all directions; the sound passed for two and a half inches. The uterine appendages could not be felt nor could the lower surface of the abdominal tumour be reached either by vaginal or rectal palpation.

In Case 2 the patient, aged 47 years, was admitted to Charing Cross Hospital under the care of Dr. Amand Routh on Oct. 17th, 1901, complaining of enlargement of the abdomen. I had previously seen her in the out-patient department, where she attended by the advice of her medical attendant (Mr. L. Potts of Leatherhead). She has been married for seven years and has never been pregnant. Her menstrual periods have never given her any trouble until about two years ago when they became profuse, lasting 14 days with an interval of about the same period. For 12 months the periods continued to be profuse, but during the last 12 months the amount has gradually lessened until at the present time the duration has diminished to seven days with 21 days' interval. About 18 months ago she became conscious of the presence of a small lump in the lower part of the left side of the abdomen. Since then she has complained of increasing abdominal pain and discomfort both on walking and on lying down, and of steadily increasing abdominal enlargement. Her general health has been fairly good and she does not think that there has been any loss of flesh. There have been no urinary symptoms and no leucorrhœa. Her past personal history and her family history present nothing of interest. She has never been very robust, and she thinks that she was usually anæmic.

On admission it was noted that the patient was well nourished but anæmic; there was a good deal of œdema of the feet and legs, which had not entirely disappeared a week after her admission, although she had been kept in bed all the time. The temperature since her admission has been a little irregular, and on two evenings has reached 99·8°F. The urine contains nothing abnormal, and the heart and lungs are healthy. Inspection shows that the abdomen is uniformly distended to a moderate extent, the greatest girth immediately below the umbilicus measuring 37½ inches. Measurements from the umbilicus to the right and left anterior superior spines are about equal, and the umbilicus is about midway between the pubes and the xiphisternal articulation. There is no bulging of the flanks. Palpation reveals the presence of a large solid tumour lying beneath the thick abdominal parietes. The extent and outline of the tumour can best be defined by palpation and are represented in Fig. 1.

FIG. 1.



Areas of dulness in dorsal position.

On percussion a resonant note is obtained over the upper third of the tumour in the middle line, showing that in this part it is covered by coils of intestine. Its lower border can be palpated just above the pubes. Over a part of the anterior surface of the tumour represented in the sketch No. 2 there is evidence of the presence of a thin layer of fluid between the tumour and the abdominal wall.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Cheques and Post Office Orders *(crossed "London* and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

**Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.**

large tumours causing great distension of the abdomen this is often impossible, and in the case under consideration we have failed to detect the presence of the ovaries in their normal position. In a woman who has ceased to menstruate for 15 years atrophy of the ovaries will have further increased the difficulty of recognising them. The only possible line of proof which remains is the recognition of the ovarian pedicle. In most cases of ovarian tumour, whether solid or malignant, the pedicle can be palpated by the following simple procedure. The cervix is drawn down with a volsellum so as to depress the uterus and to withdraw it from the abdominal tumour. An assistant then gently pushes the tumour upwards, and in this way the pedicle is stretched, and the finger passed into the rectum can recognise it or a bimanual examination may be made under favourable circumstances. In this way both the existence of a pedicle and the side to which it is attached may be recognised and the thin membranous ovarian pedicle can readily be distinguished from the thick pedicle of a pedunculated subserous fibroid.

In the case before us no pedicle can be palpated, but the distension of the abdomen is too great to permit of a satisfactory bimanual examination being made; the presence of the fluid greatly increases the difficulties of the procedure. The existence of a pelvic pedicle cannot, therefore, be excluded with certainty, so that we have carried the process of exclusion as far as we can go with certainty. A question of probability remains, however, which appears to me to determine the weight of evidence in favour of an omental and not an ovarian origin. If ovarian the pedicle must be a long one, for the growth lies above the pelvic brim and cannot be reached from below. The history of the patient's illness is short (about three months), and the growth of the tumour is therefore rapid, and its existence may be presumed to be of not more than six months' duration. Now an ovarian growth arising from 14 to 15 years after the menopause is extremely unlikely to develop a long pedicle, for the broad ligaments must have undergone considerable shrinkage from the normal atrophic processes which follow the menopause. The tumour is therefore more probably omental. (*Note.*—This patient left the hospital on Oct. 31st, having declined operative interference.)

Turning now to the second case, in which the age of the patient is 47 years, let us take up the differential diagnosis of growths of the omentum, the ovaries, the uterus, and the broad ligament. You remember that in this case a pelvic pedicle uniting the tumour to the uterus was felt distinctly; this fact almost serves to exclude growths of the omentum which, of course, have no pelvic pedicle. It must be remembered, however, that malignant abdominal tumours tend to invade neighbouring organs and in this way a tumour of abdominal origin may acquire a pelvic attachment. Such an attachment, however, would be unlikely to occur alone—i.e., without invasion of all surrounding organs, leading to fixation of the tumour. The mobility of the abdominal mass in this case renders invasion of surrounding parts extremely unlikely and the pelvic pedicle is therefore proof of a pelvic origin. Growths arising in the broad ligament may be excluded for the same reasons as those given in discussing the first case. The diagnosis therefore lies between growths of the uterus and growths of the ovary or ovaries.

It will be well first of all to indicate the general lines of proof available for the differential diagnosis of tumours of these two organs. Symptomatology in relation to abdominal and pelvic diseases practically never renders much assistance in differential diagnosis. Fibroid tumours of the uterus, although they usually cause menorrhagia, may be associated with scanty menstruation, and solid tumours of the ovary cause amenorrhœa nearly as often as menorrhagia, while frequently menstruation is unaffected by them. I profoundly distrust symptoms as an aid to diagnosis. Abdominal conditions must be recognised, and differentiated from one another by a careful study of their physical signs, without any mental bias such as a trust in symptoms often produces. The first point to which I would direct your attention is the length of the uterine cavity. Ovarian growths do not cause enlargement of the uterine cavity while fibroids usually do; therefore, if the sound passes definitely further than the normal length this point is strongly in favour of uterine tumour. The converse cannot unfortunately be maintained, for sub-peritoneal fibroids which cause no hæmorrhage usually also cause no enlargement of the uterine cavity. In the next place, if the ovaries can both be recognised in their normal position, an ovarian origin can be excluded. It must be remembered, however, that the ovaries are often much displaced by fibroid tumours, and nodules of new growth may be mistaken for them. Often palpation of the ovaries is impossible without an anæsthetic, and sometimes impossible then, but a positive result is of great value. Here, again, the converse cannot be maintained, for one frequently finds the ovaries lying behind a fibroid tumour where they would be quite inaccessible to clinical examination.

In the next place, palpation of the pedicle can be practised, and this offers the most reliable means of distinguishing uterine from ovarian tumours in the great majority of cases. The ovarian pedicle is a structure which can often readily be examined by a bimanual or rectal examination, and after a little practice can hardly be mistaken for anything else. The attachment of a subperitoneal fibroid is usually very much shorter and thicker, and feels solid rather than membranous. Occasionally such a tumour develops a membranous pedicle, but this occurrence is so rare that allowance need not usually be made for it. Recognition of the ovarian pedicle also tells the side from which the tumour springs. Interstitial fibroids can be absolutely distinguished by this method. Sometimes, however, ovarian tumours develop between the layers of the broad ligament and have no pedicle; sometimes in the case of malignant ovarian tumours secondary nodules develop in the pedicle causing it to assume the character of a fibroid pedicle. Errors arising from such occurrences as these cannot be avoided.

Lastly, ascites is the rule with solid tumours of the ovary, and with fibroids is so extremely rare that its presence almost serves to exclude them. An extended search in text-books and monographs and in the transactions of obstetrical societies has only revealed one such case, recorded by Thomas Keith, and then the ascites only developed after an injury to the tumour caused by a blow upon the abdomen.

In the case which we are now considering we have enlargement of the uterine cavity, a distinct but thick pedicle on the left, and ascites. The two latter points practically settle the question in my own mind that the principal tumour is a solid ovarian growth. But this will not explain the enlargement of the uterine cavity, which is strongly presumptive of fibroid tumour, as the patient is not, and never has been, pregnant. Further, the nodules felt in the pouch of Douglas feel very like subperitoneal fibroid growths from the posterior wall; their mobility practically excludes the possibility of their being secondary malignant deposits in the pelvic peritoneum. The conclusion seems inevitable that both conditions are present—that the main tumour is a solid growth of the left ovary, while the uterus is the seat of one or more small fibroid tumours. (*Note.*—The patient was operated upon on Oct. 30th by Mr. Stanley Boyd who removed a large solid ovarian tumour of the left side; there was also a large amount of free ascitic fluid and the uterus contained several small fibroids. The tumour was a fibroma with extensive cystic degeneration irregularly distributed through it.)

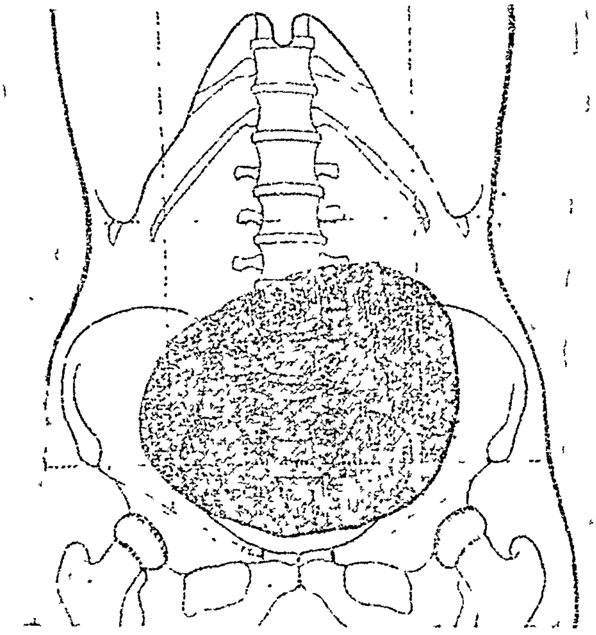
The only remaining point for diagnosis is the *nature* of the growth. In the case of an abdominal tumour it is seldom possible to say more than that it belongs either to the class of malignant growths or to that of innocent growths. Its actual structure can only be determined by the microscope.

With regard to the first case I believe that the growth is in all probability malignant. The history of the illness is very short, the patient having been in good health up to July, 1901. The tumour has, therefore, attained a considerable size in a short time, and its rate of growth must be rapid. Further, there has been considerable loss of flesh, although this does not amount to emaciation. Solid abdominal tumours, with the exception of those of the uterus and ovaries, are usually malignant, especially when accompanied by ascites. The age of the patient is not a point of much importance, but as a general rule old age is presumptive of malignancy. I do not think that much importance can be attached in this case to the presence of œdema of the lower extremities which is probably of mechanical origin, but when such œdema accompanies abdominal growths of small size it is strongly in favour of malignancy.

With regard to the second case the evidence is in favour of innocence. Although the history of the patient's illness is much longer than in the last case, amounting to about 18 months, there has been practically no loss of flesh, and with

"Dipping" can readily be obtained over this area, although the amount of fluid is not sufficient to yield a percussion thrill. Near the edge of the tumour a rounded nodule lies, just beneath the abdominal wall. A sharp push upon this nodule causes it to recede suddenly and return in a moment to the surface, giving a distinct example of "ballottement." The whole tumour is not nearly as moveable as was that in the last case where ballottement of the whole mass could be obtained. Its general outline is oval and its surface is irregular and nodular. There is very little abdominal tenderness. The total area of dulness (partial or complete) is represented in Figs. 1 and 2. The left lumbar region is, however, sub-resonant in the dorsal position and clears a good deal with the patient on the right side. With the patient on the left side the area of dulness increases considerably, as the tumour appears to fall forward against the anterior abdominal wall. The right lumbar and iliac regions are resonant in every position. From these relations it is obvious that we are dealing here, not with free ascites—i.e., with fluid free to move from one rt of the peritoneal cavity to another under the influence gravity—but with fluid limited to a great extent by adhe-, or in some other way. On vaginal examination we nd the cervix in its normal position; the uterus cannot be ed by bimanual palpation, but the sound passes and forwards for four inches. In the pouch of has a smooth solid lump of the size of a pigeon's egg felt and this can be readily displaced by a tap, giving ballottement. Fluctuation can also be felt in this fornix. As far as can be made out without anæsthetising the patient the solid abdominal tumour is continuous with the uterus. By pulling down the cervix with a volsellum and then practising rectal palpation a thick dense attachment of the tumour to the left side of the fundus can be made out.

FIG. 2.



Size and position of tumour as defined by palpation.

Let me now briefly recapitulate the results of the physical examination in the two cases. In the first case we have a solid abdominal tumour surrounded by a large amount of fluid in which it is very freely moveable. The fluid is not free but is limited by adhesions or otherwise. The uterus is small and freely moveable, and no connexion between the abdominal tumour and the pelvic organs can be made out. In the second case we have a solid abdominal tumour with a smaller amount of limited fluid, and much less moveable than the former. It is closely connected with an enlarged uterus, and there is a moveable solid nodule with fluid in the pouch of Douglas. Most of the fluid in this case appears to be in the pelvic cavity. Percussion of the liver and spleen in both cases shows that there is no enlargement of these organs.

We are now in a position to discuss the diagnosis, which I hope you will not consider a waste of time. Too often nowadays one hears the remark from an operator: "We shall know all about it when we open the abdomen." But to be unable to determine the nature of an internal tumour without first removing it is a state of affairs with which we ought not to be content. The frequency and facility with which laparotomy is now performed have led to great neglect of the art of abdominal diagnosis; and for this neglect there is no excuse, because increased experience of abdominal surgery ought to have laid the foundations for greater accuracy of diagnosis, and if the opportunities of operators had been turned to good account it would have already done so. But the slackness which is content with postponing diagnosis until after operation is as much to be deplored as is the timidity which declines the risk of being proved to have reached an erroneous diagnostic conclusion.

The number of conditions which give rise to the occurrence in the abdomen of a large solid tumour with ascites is considerable. These conditions may be enumerated thus: malignant disease of the liver, the spleen, the kidneys, the omentum, and the ovaries; innocent tumours of the ovary, the uterus, and the broad ligament (rarely); and tuberculous deposits. With regard to the two cases under consideration the list can be reduced considerably without much difficulty. Growths of the liver can be excluded by the facts (1) that there is no enlargement of that organ, and (2) that a distinct zone of resonance separates it from the tumour in both cases. Growths of the spleen can be excluded for the same reasons, with the reservation that growths arising in a displaced or wandering spleen give rise to extremely difficult diagnostic problems. Growths of the kidney can also be excluded (1) by the position of the tumour, and (2) by the healthy condition of the urine. Displaced kidneys may give rise to similar difficulties to those presenting in displaced spleen. Tuberculous deposits may in all probability be excluded (1) by the age of the patient (these deposits are rare after the fortieth year and extremely rare in old age); (2) by the size and mobility of the growth in each case (tuberculous deposits seldom form large masses and are usually more or less fixed by adhesive peritonitis); and (3) by the absence of signs of tuberculous disease in the lungs and pleura. Subnormal temperature often accompanies tuberculous disease of the peritoneum, so that the absence of pyrexia is not of diagnostic significance. These points reduce the possibility of tuberculous disease to very low limits. There remain for consideration growths of the omentum, the ovaries, the uterus, and the broad ligaments.

Let us consider first the case of the patient in Case 1, whose age was 64 years, and endeavour to decide which, if any, of these conditions can be excluded. Uterine tumours do not cause ascites, even when malignant, except in the rarest instances. Cases of degenerating fibroids with a little ascitic fluid are occasionally met with, but the amount of fluid is too small to admit of clinical recognition. Even uterine sarcomata do not cause ascites. The presence of a large amount of fluid in this case is therefore an important objection to the theory of uterine origin. Further, the absence of any discharge from the uterus, either hæmorrhagic or other discharge, is another important objection, for large uterine tumours, whether fibroid or malignant, are almost invariably the cause of discharge. Lastly, the size of the uterine cavity (2·5 inches) and the free mobility of the uterus independently of the tumour indicate that the organ is of normal size and not closely connected with it. This view is further confirmed by the fact that the tumour cannot be reached from the vagina or the rectum. The exclusion of growths from the uterus can therefore be satisfactorily accomplished.

Solid tumours of the broad ligament are either fibroid or malignant. In neither case is ascites found. The base of the tumour lies deep in the pelvic cavity and in close association with the uterine border from which it probably, in the majority of cases, arises. Cysts of the broad ligament may form a pedicle, but I have never met with a pediculated solid tumour of the broad ligament. Broad ligament growths may therefore be also excluded, leaving only two others for consideration, ovarian and omental tumours. Solid tumours of the ovary which have a long pedicle are not easily distinguished from solid omental tumours. They may occupy the same position in the abdomen, they are freely moveable, and they are associated with ascites. If the presence of both ovaries in the pelvis can be determined the exclusion of an ovarian origin is certain. But in the case of

7.50 A.M. and was completed at 12.30 P.M. Among the witnesses were the physicians who had been in attendance at the execution.

As the body lay upon the table in the dorsal position the right leg, to which the electrode had been attached, was slightly flexed and was a trifle abducted. This attitude of the body has been found to be uniform in the post-mortem examinations made on many other electrocuted criminals by Dr. Ira Van Gieson.[1] In all of these cases the electrode had been applied to the knee flexure. Corresponding to the attachment of the leg-electrode there was a superficial blistering, with some desquamation of the epidermis and some œdema. At the site of application of the head-electrode there were only a few signs of vesication, limited to the occiput. Post-mortem discolourations existed in all the extremities, but not in the trunk, head, or neck, where the skin was fairly white. There was post-mortem lividity of the toe- and finger-nails. The pressure of the straps had not produced any discolourations. There was a discharge of small amount from the urethra, probably of seminal fluid.

The assassin's physiognomy may be described as youthful and with rather a pleasant expression. The nose was pointed, slightly *retroussé*, and fairly straight, deviating a little at the point of the injury inflicted at the time of the assassination. The eyes were blue and the pupils were equal and moderately dilated. The hair was a light brown and was slightly curly. The face was oval and symmetrical. The ears were well formed and absolutely symmetrical. The mouth was well shaped and the lips were full; measuring the true orifice, the width was four centimetres, between the outer angles it was five centimetres. The teeth were of normal shape, but were in poor condition. The external genitals were normal and were unclean with accretions of smegma under the prepuce. There were two flat cicatrices, one four millimetres in diameter, the other half as much, on the mucous surface of the prepuce about five millimetres from the corona glandis. The tissues under and about these cicatrices were not indurated, and the scars were doubtlessly the remains of chancroids acquired at some time previously. As stated before, there had been a discharge of seminal fluid, some of which was still within the urethral passage. At 8 10 A.M. the surface temperature of the body, taken on the side of the chest with a "Seguin" surface-thermometer, was 97°F.; per os it was 97 4°. The body cooled very slowly throughout the examination and the greatest amount of heat appeared to be retained in the brain. Rigor mortis set in about three hours after death.

The following measurements of the head were recorded (the measurements are given in centimetres). Maximum circumference (21½ inches), 54 6; maximum antero-posterior diameter (from the glabella to the maximum posterior point), 18·7; maximum lateral diameter (cephalic index = 82·88), 15·5; bi-auricular diameter (between the roots of the zygomæ), 15·0; length of the face (from the inter-superciliary point to the superior alveolar point between the middle incisors), 9 2; bi zygomatic diameter, 14·5; minimum frontal diameter, 12 0; diameter from the glabella to the inion, 19·1; from the vertex to the hair-line, 12 0; from the hair-line to the root of the nose, 6 0; from the root of nose to its base, 5·3; from the base of the nose to the chin, 7·0; from the vertex to the chin (diameter), 25·4; breadth between the pupils of the eyes, 6·8; breadth of the nose at its base, 3·4; width of the mouth internally, 4·0; externally, 5·0; length of the ears (both sides equal), 6·1. After these measurements had been taken about 50 minutes were devoted to the making of plaster-moulds of the entire head. A cast has since been made from these moulds and two photographic views, in full face and in profile, were taken of it.[2] Unfortunately the left ear in the mould had been broken during transportation from Auburn and the fragments were pieced together with difficulty. The defects have been rectified in the photograph. On the subject the ears were perfectly symmetrical, both as to form and size. The moulds were made upon the head while the body lay prostrate upon the table. This attitude gave rise to the prominence of the "Adam's apple," and to the slight parting of the lips. The hair was rubbed well with vaseline and was flattened as much as possible to prevent the plaster from adhering. On the skull the following measurements were taken: maximum antero-posterior diameter, 18 0 centimetres; maximum lateral diameter, 14 7 centimetres; cranial index = 81 66.

The head of Czolgosz, as is typical of the Poles, falls in the sub-brachycephalic class; according to Weisbach, the cephalic index of 40 Poles was 82·9 (82 88 in Czolgosz).

At the time of Czolgosz's reception at the Auburn State Prison (Sept. 27th) the measurements of his body were taken according to the Bertillon system by J. N. Ross. I reproduce here the more important figures (the measurements are given in centimetres):—Stature (five feet seven and a half inches), 171 4; stretch, 181 0; trunk, 91·1; head—length 18 6, width 15 6; cheek, width, 14·5; right ear, length, 6·3; left foot, 26·0; left middle finger, 11·7; left little finger, 9·0; left cubit, 47·2. "These measurements are all medium and each is consistent with the others. The stretch and cubit measurements might be said to be slightly out of proportion, indicating that his forearms were slightly longer than those of a majority of men of his stature, but this excess of length is not sufficient to call for comment." His weight on that day was 141 pounds. The marks and scars are here reproduced in the order in which they appear on the identification card of the Prison Department. "I. Sev. sm. cics. post. first finger, left hand near 2nd joint. Cic. of 1 ob. ex. on 1st phal. 3rd finger left hand post. II. Cic. of 3 rec. ver. crossing 3rd joint, mid. fgr. right posterior. Cic. of 1 circ. at 5 over right wrist post. III. Mole at 5 under left cheek-bone and 9 to left med. line. IV. Sev. moles on front and back of neck."

Next the cranium was opened and the brain was removed. The scalp was divided by means of a median incision passing from the glabella to the inion. On incising the scalp a quantity of dark fluid blood escaped. The scalp was of moderate thickness, firm, and well adherent to the skull. The two flaps of the scalp were dissected from the skull and were drawn down on either side of the head. The sutures were well marked and no synostosis was observed. Supernumerary or abnormally developed bones were not discernible. The calva was removed by a saw-cut passing around the cranium about 1·5 centimetres above the glabella and about 2 5 centimetres above the inion. In the removal of the calva the saw was supplemented by the chisel and the hammer. The calva came off rapidly, the dura mater being non-adherent. There was no marked escape of cerebro-spinal fluid. Along the saw-cut the skull was slightly flatter in the fronto-parietal region on the right side, while it was more curved or rounded on the left. The right parieto-occipital region was a trifle fuller than on the left side. The markings on the internal surface of the calva, such as the groove for the superior longitudinal sinus and for the meningeal vessels, the digitations, and the impressions for the Pacchionian bodies, &c., were all distinctly marked. The dura mater was greyish-white, moderately translucent, and somewhat dry; there existed a marked engorgement of dark fluid blood. The dura mater was neither tense nor loosened. The Pacchionian bodies were of the usual number and distribution. The inner surface of the dura mater was fairly moist. There were no evidences of hæmorrhagic pigmentation or of pachymeningitis.

The brain, invested by the pia-arachnoid, was exposed by crucial incisions into the dura mater which was perfectly non-adherent to the membranes within. The brain was removed carefully and during most of the subsequent examination was kept in a salt solution (about one part in 20 parts of water). At the time of removal, still invested by the pia-arachnoid and with the ventricles unopened, the entire brain weighed 51½ ounces avoirdupois (1460 grammes). The base of the skull was normal in every respect. The pia-arachnoid was of normal thinness and devoid of opacities or other signs of disease, past or present. The only unusual appearance was an injection of bright red blood in the finer vessels of the pia, due, if we may judge from previous reports of necropsies on electrocuted criminals, to the high electromotive force exerted by the fatal current in this part of the body. The pia was stripped off with ease, being nowhere adherent to the cortex.

*Examination of the brain.*—In general the brain presented no marked peculiarities of shape or size. It was firm to the touch and no portion of it, despite most careful examination, felt softened or indurated. It was divided into its natural segments according to the following method. The ectal border of the optic tract and the tænia thalami ("ripa" of Wilder) were used as guides for a single simple incision; those of either side converge cephalad to meet in front of the chiasm; the usual cut through the callosum and the

[2] THE LANCET, Feb. 1st, 1902, p. 281.

the exception of considerable but not profound anæmia her general condition is good. The presence of ascites with solid ovarian tumours is not in the least to be understood as evidence of malignancy, for the innocent growths are invariably accompanied by it. It is a curious phenomenon in intra-abdominal disease that a solid tumour—e.g., a fibroma of the ovary—should cause ascites, while a growth of precisely similar structure in the uterus should not. As in the last case, the œdema of the lower extremities is a mechanical effect of pressure. The solid nodules felt in the posterior fornix being well defined, freely moveable in the fluid, and accompanied by no peritoneal induration, are unlikely to be secondary malignant deposits. They are in all probability small subperitoneal fibroids. This case, therefore, admits of a favourable prognosis.

# PRELIMINARY NOTE ON THE POSSIBILITY OF TREATING MITRAL STENOSIS BY SURGICAL METHODS.

BY SIR LAUDER BRUNTON, M.D. EDIN., F.R.S.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL

MITRAL stenosis is not only one of the most distressing forms of cardiac disease, but in its severe forms it resists all treatment by medicine. On looking at the contracted mitral orifice in a severe case of this disease one is impressed by the hopelessness of ever finding a remedy which will enable the auricle to drive the blood in a sufficient stream through the small mitral orifice, and the wish unconsciously arises that one could divide the constriction as easily during life as one can after death. The risk which such an operation would entail naturally makes one shrink from it, but in some cases it might be well worth while for the patients to balance the risk of a shortened life against the certainty of a prolonged period of existence which could hardly be called life, as the only conditions under which it could be continued might to them be worse than death. I was much impressed by the case of a man under middle age whom I had under my care at St. Bartholomew's Hospital. For no fault of his own, but simply because of his disease, this man was really exiled from his family and one might almost say imprisoned for life inasmuch as he could only live in a hospital ward or a workhouse infirmary. Whenever he left the hospital or infirmary with an amelioration of his distressing symptoms and returned home the exertion brought on an exacerbation and he had to leave home again in a few days to return to the hospital or infirmary. It occurred to me that it was worth while for such a patient to run a risk, and even a very grave risk, in order to obtain such improvement as might enable him at least to stay at home. But no one would be justified in attempting such a dangerous operation as dividing a mitral stenosis on a fellow-creature without having first tested its practicability and perfected its technique by previous trials on animals. Accordingly I obtained a licence and certificates a year ago in order to make the necessary experiments, but unfortunately other calls upon my time have not allowed me to do more than to make trial experiments of dividing stenosed valves in diseased hearts from the post-mortem theatre and on healthy valves in the hearts of cats, and also to try the proposed operation in the dead animal. It may be some months longer before I can get anything more done, and I therefore think that it may be worth while to write this preliminary note, especially as, after all, if the operation is to be done in man it will be surgeons who will do it, and they must, of course, make their own preliminary experiments, however fully the operation may be described by others, and each must find out for himself the method which he will employ in each particular case.

The first question that arises is whether the mitral orifice should be enlarged by elongating the natural opening or whether the valves should be cut through their middle at right angles to the normal opening. I think there can be little doubt that the former would be the better plan, but the latter is the more easily performed, and it might be sufficient to effect the desired purpose of facilitating the flow of blood from the auricle into the ventricle. The knives which I have used have been like tenotomy knives, but some which I have had made of ladies' bonnet pins were too thin and flexible for stenosed valves although they were sufficiently strong to divide the normal valves in the hearts of cats. The cutting edge of some of these was only a quarter of an inch, but this is too short and a cutting edge of from half an inch to an inch is really required. The main part of the valve can be divided with comparative ease, but the thickened edge is firm and it resists the knife. I have not yet decided on the best form of knife, and its form must depend to some extent upon whether the surgeon decides to operate from the auricle or from the ventricle. The latter is less likely to bleed as the knife need not be much thicker than a needle, and a needle wound of the ventricle rarely gives rise to any bleeding. I have often observed this in animals, especially during the experiments of the Hyderabad Chloroform Commission. The same is the case in man, whilst a needle puncture in the auricle may give rise to much bleeding.[1]

The plan which I have used (but only in the dead animal) for exposing the heart is that of Ninni of Naples, recommended by Rotter and described in the *Medical Review* for July, 1900, p. 400. In consists in making incisions from the left edge of the sternum outwards to the left along the lower edges of the third and fifth ribs, connecting their outer ends by a third incision, and dividing both the soft structures and the fourth and fifth ribs. The window thus made is forcibly turned back on the sternum, the sternal attachments of the ribs yielding to the pressure. In this way the heart is sufficiently exposed, and the lung being pushed back the pericardium can be divided and the knife can be introduced into the ventricle. I have only inserted the knife into the ventricle *in situ*, and if one wished to operate through the auricle the window would probably require to be made by an incision at the lower border of the second rib, although by pulling upon the heart it might be displaced sufficiently to allow a knife to be put into the auricle even when the incision is made at the lower border of the third rib.

In many experiments made for other purposes I have been astonished at the way in which the heart went on beating, apparently quite unaffected by pulling, compressing, or handling of any kind. In operating on the living heart the knife should be introduced during diastole, as one is less likely to wound the opposite wall of the ventricle. The pericardium should not only be opened for convenience of operation, but should, I think, be left open so as to allow any blood which might ooze out through the ventricular wound to flow away instead of remaining in the pericardial cavity, for the heart has very little power indeed to resist pressure from pericardial distension, especially if it comes on rapidly.

The good results that have been obtained by surgical treatment of wounds in the heart emboldens one to hope that before very long similar good results may be obtained in cases of mitral stenosis.

Stratford-place, W.

# THE TRIAL, EXECUTION, NECROPSY, AND MENTAL STATUS OF LEON F. CZOLGOSZ,

ALIAS FRED NIEMAN, THE ASSASSIN OF PRESIDENT MCKINLEY.

BY CARLOS F. MACDONALD, A.M., M.D.,
PROFESSOR OF MENTAL DISEASES AND MEDICAL JURISPRUDENCE IN THE UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; EX-PRESIDENT OF THE NEW YORK STATE COMMISSION IN LUNACY.

*With a Report of the Post-mortem Examination,*

BY E. A. SPITZKA,
OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

(*Concluded from p. 293.*)

## THE REPORT OF THE POST-MORTEM EXAMINATION BY MR. SPITZKA.

THE post-mortem examination was performed by me under the supervision of Dr. Carlos F. MacDonald of New York, who was requested by the State Superintendent of Prisons to take medical charge of the execution in conjunction with Dr. John Gerin, prison physician. The examination began at would be independent but for a superficial junction with the para-central. The occipital fissure was deeply confluent with the calcarine. The post-calcarine was tri-radiate and was separated from the calcarine by a posterior cuneo-lingual isthmus. The super-frontal gyrus was fairly well marked by many transverse fissures, and by two long and distinct rostral (rostral and sub-rostral) fissures. The pre-cuneus was large, a little larger than its fellow on the left side. The cuneus was as small as on the left half. The sub-calcarine gyrus was of considerable width in its caudal portion. The insula presented an ordinary degree of development and, as on the left side, it possessed six gyres, with seven peri-insular digitations.

---

[1] Medical Record, Dec. 15th, 1900.

*Section of the brain.*—In cutting the brain, the resistance to the knife suggested neither increased nor diminished consistence. The cut surface was moderately moist, the grey as well as the white matter were of normal colour, the cortex was of the usual thickness, and there existed neither anæmia nor hyperæmia. No hæmorrhages, sclerotic patches, neoplasms, or other lesions were discoverable. The basal ganglia, crura, cerebellum, pons, and oblongata were all perfectly normal, there being even an absence—so far as naked-eye examination could determine—of the small hæmorrhages in the floor of the fourth ventricle which have been usually found in electrocuted criminals.[4] The spinal cord was not examined.

*Examination of the thorax and abdomen.*—An incision was made from the top of the sternum to the pubic symphysis, a quantity of dark fluid blood escaping. The diaphragm was found to be attached to the sixth rib on both sides of the sternum. About from three to four fluid-drachms of clear fluid were found in the pericardial sac. The heart was firm and appeared to be in a tetanised condition; it had ceased in systole. This contracted condition of the heart was doubtlessly due to the high electromotive force of the fatal current. The ventricles were empty; the heart-walls, endocardium, and valves were normal. The weight of the heart was 11 ounces. Both lungs were somewhat emphysematous, floating a trifle more than half out of water. They were moderately pigmented and of firm consistency. None of the bronchial lymph-nodes were enlarged. Except for a few bands of pleuritic adhesions of the right lower lobe, there were no lesions in either lung. The left lung weighed seven and three-quarter ounces, the right lung eight and a half ounces. The larynx, the aorta, and the venæ cavæ were normal. The stomach was in the normal position, well contracted, and well under the diaphragm, with only a small residue of food near the pyloric end—the prisoner having had nothing to eat since the evening before the execution.[5] The examination of the intestines was a brief one as nothing unusual was seen. The appendix was eight centimetres in length, free, and lay dorsad and mesad of the cæcum. The pancreas was normal. The liver was dark and hyperæmic but healthy; there were no patches, infarctions, or other lesions. The gall-bladder contained about one ounce of clear bile. The liver weighed 61 ounces. The spleen was also hyperæmic, mottled with light pink streaks, but of normal structure. Its weight was seven and three-eighths ounces. The kidneys were moderately supplied with fat, markedly hyperæmic, but all the structures could be made out clearly to be of normal condition. The left kidney was somewhat larger than usual. The capsule was non-adherent in both instances. The left kidney weighed seven and a quarter ounces; the right weighed five and a quarter ounces The bladder was somewhat contracted; it was firm and contained about three ounces of clear urine. The bladder-wall and mucous membrane were normal in all respects. The prostate was rather firm but not enlarged. The urethra, testes, &c., were normal.

It had been my purpose to make a fuller anatomical and anthropometrical investigation upon the assassin, but the peculiar circumstances which arose in the matter of the disposal of the body and the anxiety of the prison warden to put the body under earth forced me to conclude my researches after having obtained the most essential data for purposes of record and future study.

The results of the necropsy can be summed up by saying that Czolgosz was in excellent health at the time of his death. There was, of course, a marked condition of hyperæmia of all the viscera, and the blood was considerably altered in that it remained fluid, doubtlessly due to the destruction of the fibrin-ferment, or of the fibrinogen, or both. These phenomena, as also the seemingly tetanised condition of the heart, have been observed by E. C. Spitzka, Carlos F. Macdonald, Van Gieson, and E. W. Holmes[6] on criminals executed by lethal currents of electricity. The external appearances of the body of the assassin, especially the facial expression, have been admirably described by Murat Halstead, who happened to be present, in a short but vivid account of the necropsy entitled, "Czolgosz after Death."

> The spectacle was interesting. The assassin had been dead but a few minutes and was lying at full length on his back on the table provided for the surgeons, his body white as marble, his face not at all distorted. One might say he was as if sleeping, but that would not describe the expression of the features, though that was almost of perfect repose. The head rested on the back part of the table so as to elevate the chin and allow the forehead to slope downward. There was no sign of a great agony; the hair had not been removed for the electrode, but was full of water from the sponge, and in disorder. If there was any mark on the head made by the deadly shock it was not visible. There was a red blotch on the right leg below the knee. ...... The strong throat, with a distinct Adam's apple, was prominent. The lips were slightly parted with more than the curl they had in life. ...... There was nothing in the appearance of the body of the emaciation from imprisonment so often referred to. Any physician would say the corpse was that of a well nourished young man. The figure was of good proportions, his limbs especially so. The arms were not muscular. Evidently he was not a man who had cultivated his muscles by exercise or expanded them by labour. The arms were of a young man of leisure—smooth, round, and fair. His hands were not in any way notable. He had high insteps, neat ankles, and long toes. The muscles of the legs were better developed than those of his arms, indicating he was swift of foot. He was not noticeably spare in body; his chest was round and symmetrical—not lean—but the ribs quite distinct. With his head thrown back, it seemed to have been well poised in life, more so than is shown in his pictures—all of which that are familiar having been taken in prison. Nothing in his face or his person gave indication of heavy feeding or drinking, or of evil indulgence. There were none of the inevitable traces of confirmed dissipation.

The question as to whether the body of Czolgosz invested a healthy mind opens up a wide topic for discussion which it is not entirely in my province, to pursue. So far as our knowledge of the correlation of brain-structure and brain-function extends, nothing has been found in the brain of this assassin that would condone his crime for the reason of mental disease due to intrinsic cerebral defect or distortion. The weight of the brain, though by itself unimportant, when considered in its other relations points to a good condition of the organ. Divested of its membranes, dissected, drained, and after being immersed in a salt solution for several hours, its weight was 1415 grammes, a trifle less than 50 ounces. This weight is even a little over the average. Giltschenko[7] *records observations upon the* weight of 102 Polish brains, the average being for males 1397·8 grammes, with an average stature of 168·12 centimetres. The development of the fissures and gyres from a morphological point of view had taken place in the direction usual in ordinary average brains. There were no marked evidences of arrested development or of pithecoidal anomalies. Generally speaking, this brain did not exhibit that especial kind of asymmetry of gyral structure in the cerebral halves that is so characteristic of the brains of highly endowed individuals. *There were many features in* the one hemisphere that were reproduced almost exactly alike in the other. The few peculiarities encountered in the course of the fissures, such as the confluence of the left pre-central, by its anterior ramus, with the super-frontal, across the medi-frontal gyrus; or the separation of the right cephalic para-central limb from its stem, while at the same time the inflected joined the para central (a feature found by me in nine out of 160 hemi-cerebra in which the inflected was present),[8] and also the smallness of the cuneus, are insignificant *so far as individual brains are concerned.*

The skull was not symmetrical, but the asymmetry was

terma (lamina terminalis) completed a tri-section which left the cerebrum (prosencephal) and brain-axis separated as nearly the ideal as could be. This mode of dissection is a modification of Meynert's plan and is a method by which each hemi-cerebrum, with the insula intact, is separated from the brain-stem; whereas Meynert by trenching round the circum-insular boundaries separates the convex cortical mass from the brain-stem plus the insula, leaving a cortical component attached to the axial structures. The Meynert method consequently does not give the weight of the cerebral hemispheres, strictly speaking. As far as the caudatum and lenticularis are concerned this would not be a serious objection; but as it also excludes the important cortical area of the insula—no inconsiderable portion of the cerebral projecting and associating tracts—it falls short of the method adopted here. After the brain had been thus dissected and drained and the pia-arachnoid stripped off the cerebrum, the segments were found to have the following weights:—Left hemi-cerebrum (without pia), 585 grammes; right hemi-cerebrum (without pia), 600 grammes; cerebellum (with pia-arachnoid), 166 grammes; and the isthmus (with pia-arachnoid), 64 grammes. A total weight of 1415 grammes, or a trifle less than 50 ounces, was thus given.

Examination of the paracocles (lateral ventricles) in both hemi-cerebra revealed the veins of the striatum (the striatal veins) injected with deep violet-coloured blood. The cornua were of normal extent and conformation throughout. The endyma was smooth, the choroid plexus was normal and contained little blood; the velum interpositum ("velum" of Wilder) was normal.

The following is a description of the fissures and gyres:—

*Left hemi-cerebrum.*—The Sylvian fissure was six and a half centimetres in length, the epi-Sylvian two and a quarter centimetres; the hypo-Sylvian was absent. The pre-Sylvian ramus was two centimetres in length and the sub-Sylvian one centimetre in length. The central fissure was fairly flexuous and ramified; it was uninterrupted throughout its length and was separated from the Sylvian by a narrow isthmus. At its ventral end the fissure terminated in a hook-like manner. The dorsal end appeared on the mesial surface. The super-central fissure was confluent with the super-frontal but was separated from the pre-central fissure The super-frontal fissure was distinct in the mid- and post-frental regions but was absent in the pre-frontal region. The three-tier type was preserved in the pre-frontal region by the existence of a medi-frontal fissural segment about four centimetres in length and which was confluent with the orbito-frontal. The pre central fissure was confluent with a small diagonal fissure and this in turn with the pre-Sylvian. It sent an "anterior pre-central ramus" across the medi-frontal gyrus to anastomose with the super-frontal fissure. The sub-frontal fissure was independent and sent off several rami into the neighbouring gyres. There was a very long radiate fissure. The pre-central gyrus was not very broad as compared with the post-central. The three frontal gyres were fairly massive and were marked by fissures which ran generally transverse. The post-central fissural complex consisted of three segments. The dorsal one was very flexuous and ramified, but independent. The middle segment was confluent with the parietal, and was only superficially joined to the third segment, the sub-central. The trans-post-central was hardly visible on the external surface, but on examination it was found to communicate with the circum-insular fissure. The parietal fissure was notable for the angle which it made with the inter-cerebral cleft, converging rapidly towards it as it passed the cauda. It communicated with the paroccipital fissure over a vadum about six millimetres in depth. Otherwise the paroccipital did not communicate with any other fissure. There were two trans-parietal fissures—the cephalic one communicating with the pre-cuneal fissure on the mesial surface. The temporal lobe was of good size and shape. The super-temporal fissure was uninterrupted throughout its length and communicated with the inter-medial over a slight vadum. The medi-temporal fissure was represented by four segments. Numerous fissures, the lateral occipital among them, marked the region of the occipito-temporal transition. The post-calcarine fissure appeared on the lateral surface for about two centimetres. The post-central gyrus was of good development and was fairly wide. The marginal, angular, and post-parietal gyral portions of the sub-parietal lobule exhibited a moderate development. The parietal gyrus was of cuneiform shape, with broad cephalad and narrow caudad. The super-temporal gyrus was very sinuous. The remaining temporal gyres were fairly wide and well-developed. The sub-calcarine gyrus was wide in its caudal portion. The cuneus was small, rather unusually so. The pre-cuneus was of good size and conformation. The para-central gyrus was of typical appearance and of the usual size. It was traversed by a well-marked inflected fissure and by a tri-radiate intra-para-central fissure. The mesial surface of the super-frontal gyrus was of moderate size and was marked by five or six transverse fissures, three of which were rami of the super-callosal. The callosal gyrus in its cephalic half was doubled by a long fissure running parallel with the super-callosal; in its caudal part it was traversed by several transverse fissures. There were two well-marked rostral fissures (rostral and sub-rostral) and a short trans-rostral. The super-callosal fissure was long and anastomosed with the para-central over a vadum of five millimetres. The para-central fissure in turn anastomosed with the pre-cuneal over a vadum of three millimetres. The occipital and calcarine fissures anastomosed freely. A "posterior cuneo-lingual" sub-gyrus tended partially to separate the calcarine from the post-calcarine. The collateral fissure was fairly well ramified. The insula exhibited a good development. There were six gyres proper with seven peri-insular digitations. The insula was completely covered by the opercula.

*Right hemi-cerebrum.*—The Sylvian fissure was five and a half centimetres in length; the epi-Sylvian, three centimetres; the hypo-Sylvian, one and a half centimetres; and the pre-Sylvian, two and a half centimetres. The sub-Sylvian was very short. The epi-Sylvian was three centimetres long and the hypo-Sylvian one and a half centimetres. The central fissure was uninterrupted throughout its length and was separated from the Sylvian by a very narrow isthmus. Its dorsal end crossed the dorsi-mesal margin. The super-central fissure anastomosed with a long super-frontal fissure but not with the pre-central fissure. The pre-central fissure joined both the trans-pre-central and the diagonal and by means of these the Sylvian cleft.[3] This fissure gave off an "anterior pre-central ramus" from which sprang the caudal segment of the sub-frontal fissure. The super-frontal fissure was long and uninterrupted, extending nearly to the frontal pole. There was no true medi-frontal fissure present. The sub-frontal fissure was in two segments, the caudal segment being confluent with the pre-central by means of its "anterior ramus"; the cephalic segment anastomosed with the orbito-frontal. Besides an independent radiate fissure there were other unnamed fissures in the sub-frontal region. There were two long sagittally directed orbital fissures; the lateral one of these communicated with the orbito-frontal. As in the left half the pre-central gyrus was rather narrow as compared with the broader post-central gyrus. The three frontal gyres were all of good width and were chiefly marked by transverse fissures. The post-central fissural complex was made up of two segments superficially confluent with each other. The dorsal segment was short. The ventral segment was longer and was confluent with the parietal fissure. The parietal fissure was uninterrupted, deep, and separated from the paroccipital fissure by an isthmus. There were a well-marked post-paroccipital fissure and one distinct trans-parietal. The super-temporal fissure was long, uninterrupted, and not deeply confluent with any other fissure. There were four medi-temporal fissural segments. The inter-medial joined the parietal. There was a fairly well-marked "lateral occipital" fissure. The post-central gyrus was fairly wide and flexuous. The parietal gyrus was wide and exhibited the same cuneiform shape as described for the left side. Of the sub-parietal gyres the angular gyrus was of fair size, while the remainder of this territory showed only a moderate development. The paroccipital gyrus was very small, but was quite flush with the general surface of the brain. The gyres of the temporal lobe showed very good development, and in the occipito-temporal transition the markings were quite complex. On the mesial surface the super-callosal fissure consisted of two segments, and there was a similar duplication of the callosal gyrus (in its cephalic portion) as has been described in the left half. A notable peculiarity consisted in the confluence of the inflected fissure with the para-central stem, while the cephalic para-central limb was separated from its stem but was joined to the caudal end of the super-callosal. There was a tri-radiate intra-para-central. The pre-cuneal fissure mass had been felt bulging through the posterior vaginal wall an attempt at delivery by means of forceps had been made, with the result that the mass protruded through the vulva. The mass, which proved to be an ovarian dermoid cyst, became detached as Dr. Haultain explored it. After delivery was effected by the forceps the rent in the vagina was packed with gauze; the patient recovered.

---

[3] Found by Sernoff in 44 per cent. of Polish brains.

Thus the most recent records only confirm the prevalent teaching that an ovarian tumour detected during pregnancy should be removed, that its removal may be the best course during labour, and that a tumour of this kind is liable to undergo in the puerperium prejudicial changes which indefinitely increase the dangers of operation. This latter teaching is strongly supported by my own operative experience which I will now relate.

### OVARIOTOMY IN PREGNANCY.

I will begin with two cases of *ovariotomy during pregnancy* in my own practice. In the first all complications and dangers were anticipated, none existing at the date of the operation. In the second torsion of the pedicle occurred and the tumour lay in a position prejudicial to labour. *In each case the complication had been diagnosed* by the patient's private medical adviser who foresaw danger.

CASE 1.—A patient, aged 29 years, who was under the care of Dr. S. T. Plumbe of Maidenhead was sent to me in June, 1897, *on account of the discovery of a tumour*, pregnancy being evident. She had been married for eight years and had borne three children—the youngest was two and a half years old—and there had been no abortions. The catamenia had been absent for 15 weeks. In November, 1896, the patient *first noticed an abdominal swelling, with much dull pain*. Dr. Plumbe had recently examined her and had detected a tumour and a pregnant uterus distinct from each other; the former had grown larger since the cessation of the catamenia. I found a freely moveable spherical cyst, as large as a big orange, *rising above the right groin*. *On its* inner side was the gravid uterus, the fundus rising three inches above the pubes. The cyst could be perfectly separated from the uterus and pushed to the right or upwards. No part of the tumour came down into the pelvis. There could be no *doubt about the diagnosis*. I had seen some bad cases where pregnancy had recently occurred, cases which will presently be referred to. It was clear that an ovariotomy would be simple if performed at once; if delayed, on the other hand, several painful or *dangerous complications* were *highly probable*. The cyst, for example, might easily have fallen behind the uterus, as happened early in the history of the next case. Then there would have been a dermoid cyst obstructing labour, a complication entailing several obvious dangers. The patient was *very strong and healthy*. The pulse was 84 and the temperature was 98° F. I therefore operated on June 17th, 1897. I exposed a dermoid cyst. On account of the nature of the tumour I enlarged the incision and extracted it entire. It is very inadvisable to sponge, mop, or *flush the peritoneum in a pregnant subject*, yet such procedures are absolutely necessary if dermoid matter fouls that serous cavity, and such an accident is always possible however carefully the trocar is manipulated. The pedicle was three inches long, anatomically it was normal and untwisted. *I ligatured the ovarian vessels and then* transfixed and tied the entire pedicle which was not broad, and I took care not to tie the ligature close to the uterine cornu. The left ovary and tube were healthy. The lower border of the great omentum had been pushed up by the tumour and was adherent to the parietes; I removed it in part after careful ligature. I closed the parietes with interrupted silkworm-gut sutures, after bringing the recti and their sheaths together with continuous catgut. The tumour contained dark-brown hair, grease, and a flat piece of bone.

The after-history of the case was that the patient made a good recovery and was delivered spontaneously on Dec. 11th, 1897, of a female child. She has borne one more since that date. I will presently speak of a remarkably similar case where I had not the opportunity of operating till after the puerperium.

CASE 2.—The patient, a married woman, aged 25 years, was sent to me by Dr. R. Purdie of Haverstock Hill on Oct. 1st, 1901, he having diagnosed pregnancy complicated by a tumour. The patient, who was married in December, 1899, was delivered of a child at term in November, 1900. Dr. Purdie used the forceps, not on account of any obstruction, but because he found the patient somewhat exhausted, whilst the pains were ineffectual and the head was arrested in the perineum. There was no difficulty in delivering the child. Recovery was rapid; the child was suckled for seven months, and the patient menstruated twice (in February and in April, 1901) during lactation. The periods did not re-appear after the first week in April, 1901. Early in August the patient had a sharp attack of abdominal pain which laid her up for two or three days. About a week later she had another attack which laid her up for a week. Since then she had no more pain, permanent or temporary. Dr. Purdie had already discovered a pelvic tumour by accident when examining her at the beginning of this pregnancy. I examined her on Oct. 1st when she was admitted into the Samaritan Free Hospital. Of the pregnancy there could be no doubt. The soft gravid uterus rose to above the umbilicus. The cervix was soft and lay high in the pelvis. In Douglas's pouch and the left fornix lay a firm mass quite immoveable. On bimanual palpation its upper limits could be indistinctly defined behind the left border of the uterus in the left iliac fossa. The patient was put under an anæsthetic, and then the presence of some kind of tumour could be more clearly defined. It was separate from the uterus and it pushed the cervix upwards and forwards—in other words, it obstructed the inlet. The tumour seemed to be absolutely fixed and was very firm. Owing to its position palpation from above and below simultaneously was not easy, so that it remained uncertain whether it was solid or cystic. Attempts were made to push up the tumour gently; it was fortunate that not much force was used. Dr. C. Hubert Roberts, Dr. F. J. McCann, Dr. C. H. J. Lockyer, and Dr. R. H. Bell examined her at a consultation. An exploratory operation was considered preferable to expectant treatment.

I operated on Oct. 15th, Mr. A. C. Butler-Smythe assisting. I exposed the pregnant uterus, passing my hand into the left iliac fossa. I detected a tumour which I partly set free from soft vascular adhesions. I object to working too much in the dark in any case, and in this instance I wished to avoid bursting the cyst (it felt clearly cystic), as wiping up fluids and flushing the peritoneum greatly add to the chances of premature labour. I therefore enlarged the incision and drew the gravid uterus forwards out of the abdominal cavity. Then I saw that the left appendages were perfectly normal. The tumour was the right ovary dilated into a small pyriform cyst and displaced to the left. Its pedicle, twisted two turns, was stretched tightly across the back of the uterus. At the twisted part the pedicle was no thicker than a No. 3 catheter and on the distal side it was full of organised clot. I transfixed, tied, and divided it. The adhesions in Douglas's pouch and at the back of the uterus bled a little. The bleeding was checked by pressing sponges down into the pelvis from which a few clots were removed. Then the uterus was reduced and the abdominal wound was closed.

The after-history of the case is as follows. The patient, a healthy young woman free from neuroses, showed no sign of shock, and flatus passed within 24 hours. On the fourth day the bowels were moved freely by a dose (one drachm) of sulphate of magnesia followed by an enema. As is usual when the pedicle has been already twisted, there was no local pain, since the tension following the ligature of a broad normal pedicle did not exist. Not the least sign of uterine contraction or of bloody or any other discharge was observed. The patient left the hospital quite strong on Nov. 6th. Until her confinement she enjoyed good health and could attend to her ordinary housework without inconvenience. On Jan. 8th, 1902, she was delivered spontaneously of a living and well-developed female child. *Thus the operation did not hasten labour* which, calculating from the first week in April, took place precisely at term. Dr. Purdie informed me that the head was on the perineum when he arrived, so that he had no opportunity for an examination. Labour was easy and the *abdominal wound looked perfectly well and* showed no sign of stretching.

This case offers two special points for comment. In the first place, attempts to push up an ovarian tumour are objectionable, and I was not in favour of such a practice even in this instance; tapping is equally inadvisable. Semon of Dantzig[11] detected a tumour in the pelvis in the third month of pregnancy, and in the sixth month he operated. The tumour was a prolapsed kidney, which it was slight and fully within the normal range of variation. An absolutely symmetrical skull probably does not exist.

---

[11] Monatsschrift für Geburtshülfe und Gynäkologie, October, 1901, p. [illegible].

It is a probable fact that certain oft-mentioned aberrations from the normal standard of brain-structure are commonly encountered in some criminal or degraded classes of society, and those who have attempted to found a school of degeneracy have endeavoured to explain crime and social wickedness as due to the "accidental persistence of lower types of human organisation." But these structural anomalies, so far as they have been described in the brains of criminals, are too few and too insufficiently corroborated to warrant us in drawing conclusions from them. Various perversions or anomalies of mind may exist in this class without presenting a uniform criminal type, either from the sociological or the anatomical aspect. Of course, it is far more difficult—and it is impossible in some cases—to establish sanity upon the results of an examination of the brain, than it is to prove insanity. It is well known that some forms of psychosis have absolutely no ascertainable anatomical basis; and the assumption has been made that these psychoses depend rather upon circulatory and chemical disturbances. So far as this question touches upon the brain and body of Czolgosz, there have been found absolutely none of those conditions of any of the viscera that could have been at the bottom of any mental derangement. Taking all in all, the verdict must be: "Socially diseased and perverted, but not mentally diseased." The most horrible violations of human law cannot always be condoned by the plea of insanity. "The wild beast slumbers in us all. It is not always necessary to invoke insanity to explain its awakening."

In conclusion, I wish to express to Dr. Carlos F. MacDonald my appreciation of, and thanks for, the exceptional opportunity afforded in the performance of this necropsy.

# OVARIAN TUMOURS AND OVARIOTOMY DURING AND AFTER PREGNANCY.

BY ALBAN H. G. DORAN, F.R.C.S. ENG.,

SURGEON TO THE SAMARITAN FREE HOSPITAL.

IN the Cavendish Lecture for 1897[1] Sir John Williams showed that ovariotomy had proved as successful during pregnancy as apart from pregnancy, whilst the mortality associated with obstetric operations undertaken in cases of labour complicated by ovarian tumour was appalling. Mr. J. Bland-Sutton[2] gives in the first of his three lectures delivered before the Medical Graduates' College and Polyclinic a graphic description of two cases of labour. In the first the fœtus was extracted through an incision in the uterus and was saved; then the tumour, which lay in the pelvis, was removed and the mother recovered. In the second the tumour was pushed up, the child was delivered with forceps and was lost, whilst on the third day ovariotomy was performed after septic peritonitis had set in and the patient died. Since those authorities wrote the above observations Dr. Orgler of Breslau has prepared a most exhaustive treatise on ovarian disease and ovariotomy in pregnancy.[3] After an abstract of previous clinical and statistical records he places before us a valuable table of 148 cases of ovariotomy during pregnancy reported between 1889 and the beginning of 1901, excluding all reports which are valueless or even likely to mislead on account of important omissions. The conclusions deserve brief notice. Only six mothers were lost (a mortality of 4 per cent.), but in only four was the fatal result clearly caused by the operation, as in one case death was due to criminal abortion during convalescence from the ovariotomy and in one the patient survived the operation three months and the cause of death was not reported. The four remaining deaths make the mortality only 2·7 per cent. Subtracting the two mothers lost not directly through the operation pregnancy was interrupted in 36 out of 146 cases (24·7 per cent.), "interruption" including not only abortion and premature labours but also the four maternal deaths from operation. Thus in 110 cases pregnancy was uninterrupted. 49 were specified as having been delivered at term and some of the remaining cases were lost sight of before delivery. Amongst the 36 interrupted pregnancies, besides the four deaths, was one case of criminal abortion not fatal to the mother, two of the induction of premature labour by obstetricians, and one of vesicular mole pregnancy. Thus, 32 cases remain where untimely conclusion of the pregnancy was due purely to the operation (22·5 per cent.). In 30 cases the ovariotomy was double; in 24 of this group pregnancy was not interrupted and the remaining six included one case where the mother died. In all the 148 cases, excepting seven, the ovariotomy was abdominal. The minority was made up of vaginal operations; in two of them the pregnancy was interrupted, in two it was specified as proceeding to term, and in the remaining three it was simply recorded as continuing after convalescence. Dr. Orgler shows that when ovariotomy is postponed till after labour abortion occurs in 17 per cent. of well-observed cases. Since the appearance of this valuable monograph Dr. J. B. Hellier of Leeds[4] has published three cases, in none of which was the pregnancy interrupted by the operation, but in one done at the sixth month a stillborn child was born at the eighth month. In October, 1901, Dr. Herbert R. Spencer[5] read before the Obstetrical Society of London notes of a fatal case of rupture of a large ovarian cyst in the first week of the puerperium. The patient had refused operation and she died just after arriving at the hospital.[6] Lowenberg[7] reports a case of acute torsion of the pedicle in the third month; double ovariotomy was performed. On the thirty-fourth day, the date at which the report ends, there was no sign of abortion. M. Puech[8] reports a case which shows, what we must always bear in mind, the perils of labour when ovarian tumour is present. The patient, a primipara, aged 26 years, was confined at term. The labour was lingering and a soft, non-fluctuating tumour filled the greater part of the pelvis. The cervix lay high up against the pubes, and a foot presented and was drawn down. At the end of two hours labour had made no progress. The tumour was tapped for diagnosis, Cæsarean section being proposed. Over 600 grammes of a puriform fluid came away. Then delivery was effected, but the child, a very big male, died during extraction. Three months later Puech successfully operated, removing a large dermoid of the right ovary full of hair and grease. Dr. J. M. Munro Kerr[9] reduced a dermoid cyst obstructing labour by pushing it out of the pelvis, the patient being under chloroform. The attempt did not succeed until the head was disengaged; then the forceps was applied and the child was extracted. Five weeks later the tumour was successfully removed.

M. Puech and Dr. Munro Kerr can justify their procedures by the results which followed. None the less do both cases teach that it is always best if possible to remove a dermoid cyst during pregnancy and many experienced operators question if it be not best to operate during labour when any kind of ovarian tumour causes obstruction. Otherwise it may be damaged by pushing and handling and may become infected in the puerperium, an accident not rare even when the tumour has not caused obstruction. Thus whilst Mr. Bland-Sutton was forced to operate, in his second case related above, on the third day of the puerperium when infection had set in, and lost the case, I likewise had to operate in a case which will presently be related two months after delivery and puerperal infection of the cyst, which had not obstructed labour. This case, too, did not end in recovery.

The most recently published instance of ovarian tumour associated with gestation is among the most remarkable within the whole literature of the subject. Dr. F. W. N. Haultain[10] attended a woman in her third labour which, when he first saw her, had lasted for 24 hours. As a soft facts of clinical experience and they afford, in my opinion, the most reasonable explanation yet offered of the strange varieties of clinical phenomena met with in these conditions. The four cases which form the subject of the present paper have been seen by me in consultation during the last year and illustrate in a very graphic manner many interesting points in connexion with word- and letter-blindness. No attempt, however, will be made to discuss each case in detail, as this would lead to a repetition of what has been done already in previous papers. I will, in the first place, simply narrate the cases without comment and afterwards will discuss only those special features of each which hitherto I have been unable to illustrate by such excellent clinical examples as these cases afford. It will be seen that many important facts observed in these cases strongly confirm the views developed in detail in previous papers on this subject.

CASE 1.—Three years ago a man, aged 34 years, had an attack of left hemiplegia with paralysis of the left side of the face, from which he had been gradually recovering and now scarcely any trace of this remained. Ever since the hemiplegic attack he had suffered from severe pain above the right eye, which disappeared about a week before his aphasic attack came on. On July 5th, 1901, about mid-day, whilst at his work, he became completely aphasic. There had been very little warning before the attack, although in the morning he had said to his brother that he did not feel quite well. There was no unconsciousness or motor paralysis. His aphasia was at first complete, both motor and sensory. He could not speak and was completely word-blind and word-deaf, so that he was entirely cut off from communication with others. He could not express the simplest idea or simplest want, nor could he interpret any communication made to him by others either in writing or by speech. There had been a gradual improvement in every respect as to the motor, visual, and auditory aphasia, and when I first saw him (on the 12th) all these defects were only partial and a considerable improvement had taken place. With regard to his speech he had still some aphasic defect, but he could express all his wants and ideas, although imperfectly. He was very frequently at a loss for the proper word, only getting it after considerable pauses and hesitation, and he often used a wrong word. With regard to the auditory aphasia there were still traces of it present. He understood on the whole what was said to him, but it seemed to require considerable effort and mental concentration on his part to grasp the meaning of what was said to him. He often asked one to repeat a sentence and sometimes did not seem to grasp clearly the exact significance of a question or statement. The word-blindness was the symptom which had persisted in the most marked degree and regarding which he had been sent specially to consult me.

On examination I found that there was no letter-blindness. He read all the printed and written letters very fluently with an occasional mistake which, however, he could always correct himself. With regard to printed words there was considerable word-blindness, but not complete. He could not read any continuous sentence, but he could pick out here and there words by sight, especially the smaller and more familiar words, but the longer words always puzzled him and he was unable to read them by sight. If one allowed him to spell them out letter by letter he could, as a rule, name the word, but was unable to do so when restricted to the use of sight alone. With written words the word-blindness was still more marked. He could only pick out very few of the written words by sight and he himself was aware that he had greater difficulties with written than with printed words. The patient being a highly educated man and knowing Greek, Latin, and French, I tested him as to his power of reading each of these languages. Greatly to his own surprise I found that he read Greek correctly and with very little difficulty. I tested him with passages from Thucydides, Homer, and Xenophon and he read them all correctly. He read somewhat slowly, making very few blunders, which he always corrected at once himself. On testing him with Latin I found that though he did not read this so correctly as the Greek, he read it much more fluently and correctly than the English and that he was able to recognise by sight a much larger number of words. Many long Latin sentences he read without a pause, only now and again he failed to recognise a word by sight and had to spell it out letter by letter. French he did not read so well as Latin, but he read it better than English, being able to pick out by sight alone a much larger number of words. Thus of the four languages which he knew his word-blindness extended only to three of these, his power of reading Greek remaining intact. Of the three languages affected—viz., Latin, French, and English—the degree of word-blindness was not the same in each, being greatest with English, less with French, and least of all with Latin. In the last tongue the word-blindness was only very partial and he was often able to read whole sentences without a mistake. He read numbers with perfect fluency and correctness, both individually and in the most complex combinations. He performed sums in addition and subtraction correctly, but failed with multiplication and division, seeming to have great difficulty in remembering the multiplication table. He read musical notes as fluently and correctly as ever he did, without manifesting the slightest hesitation. He wrote to dictation, but not with perfect fluency and correctness. He evidently did so with considerable difficulty and made a good many mistakes. There was no ocular symptom or defect. There was no change in the visual fields and no abnormality in the fundus of the eye. The pupils were equal and the pupillary reactions were normal. The knee-jerks were active and there was no paralysis or paresis. The occurrence of these cerebral symptoms in a young man, 34 years of age, with healthy heart and kidneys, and the history of the antecedent attack of hemiplegia three years before, made me strongly suspect syphilitic disease of the cerebral blood-vessels and he was put upon an energetic course of specific treatment, both mercury and iodide of potassium. He was strongly urged to take complete cerebral rest. I saw this patient again on August 27th after an interval of about six weeks and found that there had been a continuous improvement as regards his word-blindness. Printed and written English words were now read with perfect correctness, though somewhat slowly and with evident effort. If he made an occasional mistake he always corrected himself when his attention was called to it. A similar improvement was found in his other languages. He read French, Latin, and Greek more rapidly and fluently than before. The patient informed me that the reading of Greek and Latin did not require such a great mental effort as the reading of English and did not take nearly so much out of him, as he expressed it. When I saw him finally (on Sept. 28th) all trace of word-blindness had disappeared and he now read English as rapidly and fluently as the other languages, but he still maintained that it required a greater mental effort and greater mental concentration to read English than to read Greek and Latin, both of which he read with a greater sense of confidence and ease. There had been a continuous improvement in his condition in other respects also. He was now much better at arithmetic and performed sums in multiplication and division fairly well, although somewhat slowly. He wrote to dictation more rapidly and with fewer mistakes, but still not with perfect correctness. There was also marked improvement with regard to speech, but traces of his aphasia still occasionally manifested themselves. Sometimes he spoke very fluently, but now and again he was at a loss for the proper word. Traces of his word-deafness were also manifest in his occasional difficulty in clearly apprehending what was said to him, necessitating the repetition of a statement. He had continued his specific treatment steadily during all this period.

CASE 2.—On the evening of July 10th, 1901, a man, aged 57 years, came home from business, had tea, looked over the newspapers according to his usual custom, and then went to the bowling green. Whilst engaged at the game he felt something wrong with his vision, had some difficulty in seeing the mark, and suffered from a slight frontal headache and some mental confusion. He managed, however, to finish his game without interruption. When he got home he took up the newspaper before going to bed, but found that he could not read it. He got up on the following morning feeling all right and took a good breakfast. After breakfast he took up the newspaper again, but found that he could not read a word, and so at his daughter's request his medical attendant, Dr. David Watson, was sent for, who took me along to see his patient two days after the onset of his trouble.

On examining the patient with the test types on July 12th I observed that he always carried the test card well to the left of the middle line before he attempted to read it. I therefore at once examined his visual field and found that the right half of each visual field was absent—i.e., he, thought advisable to remove. Pushing or tapping might have caused grave results. Mr. Bland-Sutton[12] insists in his lectures already alluded to that pushing an ovarian tumour out of the pelvis during labour is "decidedly in opposition to all the canons of surgery." In the second place, I wish to insist on the necessity of drawing the uterus well out of the abdominal incision when there is the least doubt of what is behind it. There is little chance of causing abortion if the uterus be well protected with pads anteriorly; but if the uterus be not drawn out the operator will be forced to keep moving his fingers behind it for some time and to drag unnecessarily on the appendages—manœuvres well calculated to set up uterine contraction.

### OVARIOTOMY AFTER PREGNANCY.

The result of operating in these cases was quite satisfactory. I find 15 cases of ovariotomy performed by myself where pregnancy had existed recently and the tumour was known to be present before labour. I exclude about three times as many cases where pregnancy had occurred within three years of the operation but where, when no complications were present, it was probable that the ovarian tumour had developed after the last labour and where when complications were present they might have developed later than the last puerperium even if the tumour had actually existed during the last pregnancy. Out of the 15 no complications (twisted pedicle, adhesions, &c.) were found at the operation in three. But in one of these abortion at the third month had occurred six months before I operated, and the cyst was then very large. Another case aborted in the middle of the fourth month from twisted pedicle. Thus there were two abortions in 15 cases. In two cases the patients had been twice pregnant since the diagnosis of the tumour. In eight cases, including the patients who had been pregnant twice, delivery was normal and at term, in one lingering at term, and in two instrumental at term. In two cases delivery was premature; in one of these labour, which took place at the seventh month, was very lingering, and severe peritonitis followed. I operated within three months and found the pedicle twisted and strong visceral and parietal adhesions. In one of the two cases in which the patients were known to have been pregnant twice the pedicle seems to have twisted slowly during the second puerperium with little or no pain. There were strong adhesions. The second case looked worse in this respect than it proved to be when I operated six months after the last confinement. The patient in this case was 25 years old and had long refused operation. The tumour was detected on the left of the uterus by Dr. W. I. Watson of Wellingborough during the first pregnancy, which ended normally, two years and one month before I removed it. Strange to say, though the tumour retained its position on the left side of the abdomen through both pregnancies and could not be pushed to the opposite side, I found that it was perfectly free from adhesions and bore a moderately long pedicle. It contained four pints of clear ovarian fluid and only weighed six and a half ounces. The history led one to suspect that it must be held to the left by adhesions. In no less than 11 out of the 15 cases I found the pedicle distinctly twisted and in six of the 11 the tumour was a dermoid. In one the pedicle had yielded and the tumour was nourished by omentum. The tumour had been diagnosed one month before her last delivery which occurred at term 11 months before I operated. The patient, who was 29 years of age and had borne seven children, suffered little from her tumour which held 14 pints of dark-brown ovarian fluid. In five of these 11 cases there was no further complication besides the twisting of the pedicle; the case of yielding of the pedicle is included in the five, and in the other six cases the patients suffered the usual painful symptoms of axial rotation. In seven out of the 15 cases I found strong adhesions; in six of the seven the pedicle was twisted, so these six also come under the last heading. In one of the seven cases the pedicle was not twisted; the operation was performed three months after delivery at term. There was a strong parietal adhesion, hard to reach and to separate close to the liver, and the cyst wall was dull through plugging of its vessels, but the contents were clear and sweet. In six cases the separation of adhesions gave great trouble, especially in the case of one patient who had been pregnant twice during the existence of the tumour, mentioned above as an example of painless twisting of the pedicle, yet the adhesions showed that extensive peritonitis had occurred. In one of the six cases the operation was followed by fatal results, making one death in 15 cases. A live child had been delivered at term with the forceps; the tumour was not apparently impacted in the pelvis, but it seems to have been roughly handled. As in Mr. Bland-Sutton's case, related above, it became infected during the puerperium two months before operation. Under the care of Dr. H. J. Ilott of Bromley the patient improved a little, but the temperature remained high and she was very sickly when I operated. I found universal adhesions, involving the parietes, the omentum, the ascending colon, the cæcum, the vermiform appendix, the bladder, the opposite tube and ovary, and especially several coils of small intestine, which were deeply injected. The pedicle was strongly twisted and the cystic fluid was very fœtid. The peritoneal cavity was flushed with saline fluid after careful repair of the damaged serous coat of one of the separated coils of small intestine. The patient died on the sixth day after the onset of symptoms from bacillus-coli infection—sickness, free passage of fœtid flatus, diarrhœa,[13] and tympanites, a complication frequent after separation of intestinal adhesions in ovariotomy where malignant or strongly adherent dermoid tumours are removed. This case was an eminently instructive example of puerperal infection of an ovarian cyst. Any pregnant woman with a cyst has this danger in prospect—a fact never to be overlooked in dealing with a pregnancy thus complicated. Another of the six cases where adhesions were dense is instructive on account of its strong resemblance to Case 1, where I operated during pregnancy. The patient was 30 years of age and had borne two children, and she was very strong and healthy. When I operated she had been delivered at term six months previously, and Mr. Chune Fletcher informed me that she had suffered from retroversion of the gravid uterus during the last pregnancy. Acute abdominal pain set in shortly after convalescence from the puerperium. The tumour was a dermoid closely packed with greasy hair and dull red fluid mixed with half liquid fat came away on tapping one loculus. There were very intimate adhesions to the parietal peritoneum over the bladder and to the peritoneum of the right iliac fossa. The pedicle was tightly twisted for two turns, and therefore it was easily secured and divided; then I found that the lowest part of the tumour was adherent to the front of the uterus and to some small intestine. This adhesion had to be transfixed and tied as though it were a pedicle. The peritoneum was thoroughly flushed with saline solution, some of which was left in when the abdominal wound was closed. The patient made a good recovery. Had I waited to operate on Case 1 till after labour similar complications might have been very probably encountered. Let it be noted that in both the tumour was a dermoid, full of grease; that twisting of the pedicle is exceedingly frequent in the puerperium, as the above records show; that dermoids are specially liable to this accident; that bad adhesions often follow torsion; and that separation of the wall of an adherent dermoid always involves distinct risk. Thus in 15 cases with a very clear history of recent pregnancy the proportion of complications, obstetrical and operative, was very high. This experience supports Dr. Orgler's conclusion that postponing the operation till after delivery exposes the mother to considerable danger during pregnancy, labour, and, above all, the puerperium.

Granville-place, W.

# FOUR CASES OF WORD-BLINDNESS.

BY JAMES HINSHELWOOD, M.A., M.D.,
F.F.P.S. GLASG.,
SURGEON TO THE GLASGOW EYE INFIRMARY AND CLINICAL ASSISTANT
TO THE REGIUS PROFESSOR OF MEDICINE IN THE
UNIVERSITY OF GLASGOW.

I HAVE already published in the columns of THE LANCET[1] five different papers dealing with varieties of word- and letter-blindness, in which certain views have been expounded in explanation of the highly interesting but often complex phenomena which are met with in these cases. These views, though speculative in character, are based entirely upon the numbers fluently, her power of interpreting them was a marked contrast to her complete word- and letter-blindness. She had great difficulty in naming objects shown to her—i.e., she had visual aphasia. For example, when a spoon was shown to her she could not name it, but said, "Of course, I know what it is, but cannot name it," and the same with my watch and various objects which were shown to her. I showed her also pictures of a sheep, a horse, and a dog, but she could not name any of them. There was no object-blindness, however—i.e., when she saw an object, although she could not name it, she recognised its true character and appropriate uses. She recognised her acquaintances as well as ever but could not name them. There was no loss of memory for places and she could find her way about as well as she ever could. As 14 months had elapsed since the cerebral attack, and as there now seemed to be no active disease in the brain, I strongly recommended her medical adviser to begin a course of re-education. I recommended that she should begin to learn the alphabet and to read small words just as you would teach a child to read. In fact, I have found that it is best for the patient to make use of the graduated primers which children use at school. In learning the letters I have found letter-blind patients much helped by making use of block letters, so that the sense of touch in handling the letters helps to strengthen the visual impressions and thus enables them to be acquired more rapidly. This course has been adopted, and I am informed by Dr. Semple that after two months' practice the results have been very satisfactory and encouraging, the patient being now able to recognise all the letters of the alphabet and also most of the small words in the child's first reading-book.

---

[12] THE LANCET, Feb. 9th, 1901, p. 382.

[13] See Vautrin. L'Infection Colibacillaire en Chirurgie Abdominale, Revue de Gynécologie et de Chirurgie Abdominale, November–December, 1901, vol. v., p. 935.

[1] THE LANCET, Dec. 21st, 1895, p. 1564; Nov. 21st, 1896, p. 1451; Feb. 12th, 1898, p. 422; Jan. 14th, 1899, p. 83; and May 26th, 1900, p. 1506.

Of these four cases, Case 1 presents the most novel and interesting features in the partial character of the word-blindness. In the case of an individual knowing more than one language, can he become word-blind to one language alone, leaving the others intact? Or if the word-blindness extends to all the languages with which he is familiar, may it vary in degree in the case of the different languages? Case 1 is, I think, a very important one in giving a definite and affirmative answer to these questions. The facts were observed with great care and the patient, a highly intelligent and educated man, was therefore able to render every assistance in making our examinations accurate and reliable. The patient, who was familiar with four languages, English, French, Latin, and Greek, had soon discovered for himself the painful fact that he could no longer read English; but neither he nor his medical attendants had ever thought of testing his power of reading the other languages with which he was familiar. When I put a Greek book into his hand he was both surprised and delighted to find that he could read it correctly. I made him read passages from Homer, Xenophon, and the New Testament, all of which he did correctly. It was evident, then, that so far as Greek was concerned there was no evidence of word-blindness. I then tested him with Latin and found that here there were evidences of partial word-blindness, although the great majority of words he read correctly by sight. Now and again he came to a word which he did not recognise by sight and which he had to spell out letter by letter before he could interpret it. Although he did not read Latin with the absolute correctness and fluency with which he read Greek, his reading was a very marked contrast to his almost complete word-blindness for English. On testing him with French a greater degree of word-blindness was manifested than in the reading of Latin, but still it was not nearly so pronounced as that manifested in the reading of English. He recognised by sight a large number of French words, although he made many mistakes, and many of them he could not recognise at all without spelling them out letter by letter. It will be observed, however, that even with English the word-blindness was not absolutely complete and there was no letter-blindness, thus showing that the interference with the functional activity of the centre was only of a very partial character. He knew all the letters of the alphabet and could pick out by sight a word here and there, especially the shorter and more familiar words, such as *the*, *to*, *of*, &c., but he could not read a single sentence by sight. He could only read if you allowed him slowly and laboriously to spell out each word letter by letter and thus interpret the words by appealing to his auditory memory. Thus of the four languages which he could read the word-blindness extended only to three, and the degree of word-blindness was very different in each of the three languages affected, being greatest in English, less in French, and least in Latin. The Greek language had entirely escaped, and no trace of word-blindness was manifest so far as it was concerned.

These phenomena, which at first sight may seem strange and inexplicable, are in perfect harmony with our knowledge of the brain and afford yet another clinical proof of the correctness of the views expounded and developed in my book on "Letter-, Word-, and Mind-Blindness,"[2] that "all the varieties of word-blindness met with in clinical experience can be intelligibly explained by regarding them as disorders of the visual memory produced by lesions affecting more or less completely a definite area of the cerebral cortex in which are preserved these past visual impressions arranged in definite and ordered groups."

In the case of a person who is able to read several languages the letter- and word-visual images of each language will be grouped together, forming thus a series of separate groups within the centre. If the whole centre is destroyed or its functional activity abolished the individual will be word-blind to all languages, but if there is only a very partial interference with the centre then the word-blindness also may only be very partial and may be limited to a single group of these visual images—i.e., to a single language. Hence this, at first sight, singular phenomenon of an individual being word-blind to one language and not to another is just what we would expect from the views already enunciated as to the separate grouping of the visual images within the visual-memory centre.

Although this is the first case in which I have met with different degrees of word-blindness in different languages I had already met with a case in which a patient knowing two languages was word-deaf to one but not to the other. This condition, of course, is easily explained in the same way as the partial word-blindness—viz., that in the auditory memory we have the different languages arranged in separate groups, and hence in a partial lesion one group may be interfered with or destroyed whilst the others are preserved. The patient referred to was a teacher of French in Glasgow. Manifesting certain cerebral symptoms he resigned his position in Glasgow on my advice and returned to France, where he died about a year later, right-sided hemiplegia and some degree of aphasia having manifested themselves before his death. His wife wrote to me after the event and mentioned as a very curious fact that for some time before his death he could not understand French, his native tongue, but could only understand what was said to him in English; or, in other words, he was word-deaf to French but not to English. This partial word-deafness is an exact analogy to the partial word-blindness manifested in the present cases and can be explained in precisely the same way.

The records of such cases of partial word-blindness are, however, exceedingly rare. In my book on Word-Blindness[3] it is stated "that there are partial cases of word-blindness, when the patients are able to read only some words and some letters. The inability to read may embrace all the different words and letters known to the patient, but this is not always so. Michel[4] quotes a case where the patient could read the Gothic but not the Latin characters. Charcot[5] records a case where the patient, knowing French, German, Spanish, Latin, and Greek, lost the memory of a few of the Greek and German characters only." The present case affords an excellent clinical example of the possibility of the visual word-memories of one language being preserved whilst those of the other languages known to the individual may be materially interfered with or even completely lost. Case 2 affords a further example of the peculiar varieties of partial letter-blindness. On my first examination there was a very marked difference between his power of reading printed and written letters. He read all the printed letters fairly well with an occasional mistake, but with the written letters his failure to read them was very striking. He read correctly a few of the written letters, but he made numerous mistakes and was quite unable to read a great number of them. In short, he could read the printed letters, but had a considerable degree of letter-blindness with respect to the written letters. As the patient's condition improved this letter-blindness to written characters rapidly passed off. I had right lateral homonymous hemianopsia. It was found on further examination that the patient was word-blind but not letter-blind so far as printing was concerned. He read printed letters fairly well with an occasional mistake, which he always corrected himself after a little hesitation. He could not read words, however, unless he was allowed to spell them out aloud letter by letter. He could then name the word by appealing to his auditory memory. He could not read words by sight unless in the case of a few short familiar words which he was able to pick out without spelling, such as his own name, *the, to, on, in,* &c. His word- and letter-blindness was much more complete to written than to printed characters. He did not read the individual written letters with anything like the same fluency or correctness with which he read the printed ones. He made numerous mistakes and often found it impossible to name an individual written letter. He was absolutely word-blind to written words, not being able to read by sight even the smallest and most familiar words. He could read numbers fairly well with an occasional mistake, which he was able to correct himself if he got time; the more complex the number the greater the difficulty he experienced. Groups of numbers up to tens of thousands he read fairly correctly, but in dealing with hundreds of thousands and millions he become somewhat confused. He performed simple sums mentally fairly well. He wrote correctly to dictation, but could not read what he had written. His wife informed me that the day after the occurrence of the word-blindness he wrote a letter to her at the coast, written and spelt quite correctly, as if there had been nothing wrong with him. There were no speech difficulties whatever to be made out on the most careful examination. The patient's general health had been good. In the course of his business he consumed a fair amount of alcohol each day, but without becoming intoxicated He had occasional epileptic fits for three years after his marriage, but none since. His vessels were atheromatous. His knee-jerks were exaggerated, but no other nervous symptom was discoverable. I re-examined the patient two days later. On taking the visual field I found that the hemianopsia had largely disappeared, although the right half of each field was still considerably constricted. The patient showed decided improvement in reading printed letters and words. He read the letters more rapidly, with less hesitation and with fewer mistakes. With regard to printed words he also showed improvement. Although unable to read a sentence by sight alone he was now able to read by sight a greater number of words than formerly. He had made marked progress in the reading of written letters since his last examination. Two days before he could recognise correctly by sight only very few written letters, being almost completely letter-blind for writing, but on this occasion he read all the written letters quite as readily and as fluently as the printed ones. He had made scarcely any progress with regard to written words and was practically completely word-blind in this respect. He read numbers even more fluently and correctly than on the last occasion. The last time he read fairly up to tens of thousands, but he could now read quite fluently up to millions. He felt quite well, slept well, and had no headache. His wife informed me that his memory showed no signs of impairment in other respects. He had given them many minute instructions about his business, which showed that the acuteness of his memory for facts was unimpaired. Ever since that date I have examined the patient at frequent intervals. The constriction of the visual fields gradually became less, and on August 21st both visual fields were found to be normal. There was a gradual improvement in his powers of reading This improvement was most rapid in the case of printed words and much slower in the case of written words. The number of printed words which he could read by sight steadily increased until on the 21st, about six weeks after the onset of his trouble, he was able to read sentences from the newspaper, but very slowly and with mistakes, which he was always able to correct when his attention was called to them. A month after this (Sept. 17th) he was reading even more fluently than before and with fewer mistakes. Still his reading was not normal. It was only accomplished very slowly and deliberately and evidently with great mental effort. He made steady improvement also in his power of reading written words, but his progress here was much slower. On the 17th I found that he had much greater difficulty with written words and made more numerous mistakes. He himself was well aware of this. He read all combinations of numbers fluently. He performed arithmetical problems with increasing rapidity and correctness, but still he made mistakes, especially in multiplication and division, and his results, though often correct, could not be relied upon. I was informed by Dr. Watson that on Oct. 31st he was back at his business and that all symptoms of his word-blindness had passed away.

[5] Clinical Lectures on Diseases of the Nervous System, vol. iii., New Sydenham Society's Series.

CASE 3.—On Sept. 2nd, 1900, while holiday-making in the country, a man, aged 60 years, was seized, when out walking in the garden, with a "giddy attack," but he was able to get into the house without falling. Thereafter there gradually developed some mental obtuseness and some inability to see and to speak properly. There was no motor paralysis. After a week or ten days' rest in bed his recovery seemed fairly complete with the exception of a complaint that he could not see well. His medical attendant, Dr. William MacLennan, at first thought that it was his eyes which were at fault, but at the end of September, on his return to Glasgow, Dr. MacLennan found that he was suffering from letter- and word-blindness, and accordingly brought his patient to visit me on Oct. 7th. He informed me that the patient was recovering from his word-blindness and that the condition was not now so complete as when he first saw him.

On testing the patient with letters I found that he could recognise most of them. He recognised them, as a rule, only after considerable hesitancy and difficulty, but in the long run, if he got sufficient time, he named them correctly. There were curious variations in his power of naming the letters, as at one time he was not able to name a letter and then a short time afterwards he was able to do it. On testing him with words his power of reading at sight was found to be very defective. In fact, he could not read by sight a single sentence. He could pick out by sight only an occasional word here and there. Other words he could read if one allowed him slowly and laboriously to spell them out aloud letter by letter, but if one confined him to visual recognition of the words he was unable to interpret them. He read figures more fluently than words and letters, but made mistakes with them also. There was no aphasia and no general loss of memory or defect of intelligence. I saw him again 12 days later and found an improvement. He recognised the letters much more rapidly and with fewer mistakes than before, so that his letter blindness had almost passed away, but his word-blindness remained much the same. He was put upon biniodide of mercury, and Dr. MacLennan reported that his recovery was steady, and that by the end of January, 1901, he was able to read with comparative fluency, and, in fact, that his word-blindness was practically gone. About the middle of March his medical attendant was suddenly summoned and found that the patient had had a fit. He had thereafter several severe epileptiform convulsions, not distinguishable in any way from ordinary epileptic seizures. There was no knowledge of these occurrences on the part of the patient. Recovery took place without any motor paralysis, but all the other symptoms were greatly aggravated and much worse than after the primary attack. There were now complete word- and letter-blindness and inability to read figures and to write. There were considerable mental obtuseness and general failure of memory and loss of flesh. The patient, I am informed, has remained in this condition ever since.

CASE 4.—In July, 1900, a lady, aged 34 years, became suddenly unconscious and remained so for several days. On regaining consciousness she was found to be paralysed in the right arm and the right leg and to be completely aphasic. She could neither speak nor understand what was said to her. She has gradually recovered the use of her arm and leg and of her power of speech. When I saw the patient on Sept. 11th, along with her medical attendant, Dr. Miller Semple, there was no paralysis although both knee-jerks were considerably exaggerated. There were no traces either of motor or of auditory aphasia. She expressed herself fluently and correctly and seemed to have no difficulty in understanding what was said to her. On taking her field of vision the right half of each field was found to be wanting—i.e., she had right lateral homonymous hemianopsia. She was completely word- and letter-blind both to printing and writing. The most familiar words, *the, of, to, in,* &c., she could not recognise, nor could she recognise a single letter of the alphabet. She could recognise very simple combinations of figures, but with occasional mistakes and often only after pausing for a time and evidently with considerable effort. Some numbers, on the other hand, she recognised in a moment. Although, therefore, she was far from reading been trifling the tertiary symptoms may be peculiarly severe. Nor is this to be wondered at when we consider that these patients have received little or no treatment whatever until the serious later manifestations of the disease show themselves. Hence I think it is a pretty safe rule even in the complete absence of positive evidence, to put the patient on specific treatment if there is the slightest possibility of the taint having been contracted. In Case 1 the age of the patient still a young man and the fact that he had had cerebral symptoms three years before, made it exceedingly probable that his symptoms were due to syphilitic disease of the blood vessels. The very rapid improvement under specific treatment strongly confirmed this opinion. By specific treatment I mean that the remedies should be pushed boldly, and I hold that the patient should get the benefit of the mixed treatment both by mercury and iodide of potassium. I give the mercury either by the mouth or by inunction in sufficient doses to touch the gums gently and iodide of potassium in large doses from 20 to 30 grains, thrice daily. I find that these large doses are better tolerated than the smaller ones and experience has convinced me of their superior efficacy. The treatment is to be stopped if there are no signs of improvement within a reasonable time.

Can anything be done in that other class of cases where the cerebral tissue has been destroyed and where, therefore there is permanent loss of the visual memories of words and letters? The only course to be employed in such cases is re-education. This however should not be begun too early after the onset of the cerebral lesion or so long as there are any traces of active cerebral disease present. When we are persuaded that all active cerebral disease has disappeared then we may begin to attempt the re-education of the patient. The patient must be taught to read, first learning the letters of the alphabet and then learning to read by means of the graduated primers in the same way as children are taught. That a fresh area of the brain may be educated to perform the function previously discharged by another area is, I think conclusively proved by Barlow's case[11] which I quoted in the second chapter of my book. The patient, a boy suffering from heart disease had an attack of aphasia from which he gradually recovered. He had later a second attack of aphasia which remained permanent. An opportunity occurred later of examining the patient's brain when it was found that there had been embolism of the artery supplying the left third frontal convolution and later an embolism of the vessel supplying the right third frontal convolution. The recovery from the first attack of aphasia must have been due to re-education of the corresponding brain area on the right side, but when this centre had been destroyed the loss became permanent.

So with word blindness the visual memories of the signs of language as has been stated in previous papers in THE LANCET are deposited in the angular and supra-marginal gyri of the left hemisphere but when this is destroyed there is a possibility of re-acquiring them and storing them in the corresponding area on the right side of the brain. The chances of success will be greater with young patients, as the younger the individual the greater are the capacities of development of nerve cells and nerve fibres.

In the first case which I reported seven years ago,[12] and in which the patient was a man 58 years of age completely word and letter blind re-education met with partial success. After six months daily practice he learned again to recognise the letters of the alphabet but he never learned to read by sight. He was never able to re-acquire the visual memories of words or at the most only of a very few of the short familiar ones. He could only read by spelling out each word letter by letter and thus appealing to his auditory memory. He thus made little progress beyond acquiring the visual memory of letters. After labouring at this for a year he came to me one day and said that he had given the task up. It took so much out of him as he expressed it and required such intense mental effort and he was making so little progress that he felt constrained to abandon any further efforts towards learning to read. I had recently an opportunity of examining him and found that he had again lost the visual memory of letters which he had acquired with so much effort. He was now completely letter blind as well as word blind. The visual memory of letters which he had acquired with so much difficulty had been lost completely in a few years from want of practice. This was in striking contrast to the visual memory of figures which had never been affected and which remained quite intact although never exercised during the last seven years. He read figures up to millions with correctness and fluency. This shows that the visual memory is less receptive late in life and that the impressions made are not so permanent. Five years' interval had completely effaced the visual memory of letters which had been re-acquired with great labour, but after seven years interval the visual memory of numbers remained intact because the latter was acquired at an early period of life when the cerebral cells have great powers of receptivity. His case however was so far encouraging, as it showed the possibility of re-acquiring by practice the visual memory of symbols which had been obliterated by disease. In the case of a younger patient the prognosis is decidedly more hopeful. An opportunity of putting this to the test was recently afforded me by Case 4 which I saw in consultation with Dr Semple on Sept 11th 1901. This woman, aged 34 years had been completely word and letter blind for a period of 14 months. So complete was the letter blindness that she could not recognise a single letter of the alphabet. I recommended that she should attempt to read again, practising regularly every day. This has been done and as I have just heard from her medical attendant with the most promising results. She has not been able to practise long at a time because it seems to exhaust her mentally—just the same complaint as in my other patient. She has, however, in two months made considerable progress, being now able to read all the letters of the alphabet and to recognise by sight also small words of two and three letters. She is able to read the simple sentences in a child's primer. This result is most encouraging and there is every reason to hope that she will yet regain the power of reading which had been lost by the destruction of the visual memory centre on the left side of her brain.

In another class of cases to which I have recently directed attention[13] under the term "congenital word blindness" where children born with a defective visual memory centre experience the greatest difficulty in learning to read, I have shown what can be done by determined and persevering effort steadily directed to their education and Mr E Nettleship[14] in a recent paper has confirmed my views on this subject. These patients have no doubt the great advantage of youthful brains, when the power of receptivity is greatest. Still the success achieved in these cases should further encourage us, even in the case of adults to persevering effort in the attempt to re-educate the patient and to re-imprint in the brain the visual memories of words and letters which have been blotted out by disease.

Glasgow

# A CASE OF TUMOUR OF THE LEFT PRE-FRONTAL LOBE REMOVED BY OPERATION.[1]

By WILLIAM ELDER, M.D., F.R.C.P. Edin.,
PHYSICIAN TO LEITH HOSPITAL

AND

ALEXANDER MILES, M.D., F.R.C.S. Edin.,
SURGEON TO LEITH HOSPITAL; ASSISTANT SURGEON, ROYAL INFIRMARY, EDINBURGH

THE following case presents features which appear to us worthy of being recorded. In spite of the advances made in cerebral surgery in recent years a very small number of the successful operations have been performed for tumours. This is due chiefly to the fact that very few cerebral tumours even if they can be accurately diagnosed and located are removeable. Starr has published a table of 1100 cases of cerebral tumour reported by several well known observers which shows that only 7 per cent. were "probably removeable." The difficulty in localising cerebral tumours is still very great in spite of recent advances in our knowledge of cerebral anatomy and physiology. If situated in the Rolandic area in any of the speech centres or in the occipital lobe symptoms are produced which afford great had already called attention to the possibility of this condition in Chapter IV. of my book, where I mention a case of Bruns and Stoelting,[6] in which the patient's inability to read printed letters and words was complete, but only incomplete for written characters. This case forms the antithesis of my own. In Case 3, also, it was observed that the word-blindness was more complete with regard to written words than it was with regard to printed words.

[14] Ophthalmic Review March 1901

[1] A paper read before the Edinburgh Medico-Chirurgical Society on Jan 1 th 1902.

Of these four cases of word-blindness, in one only (Case 4) did it extend to the reading of figures. In Case 1 the patient read figures with perfect fluency and correctness. In Case 2 the patient read figures with an occasional mistake and with some effort, but in a manner which formed a marked contrast to his complete word-blindness. In Case 3, although the power of reading figures was impaired, the patient read them much more correctly than words. I have elsewhere[7] discussed at length the frequency with which the power of reading figures is retained when the power of reading letters and words is lost more or less completely. These cases confirm the view of the complete functional independence of the visual memories of letters and figures and the inference which logically follows—viz., that these groups are deposited in distinct but probably adjacent areas of the cerebral cortex.

I would also call special attention to the fact that in Case 1, although the patient was word-blind, he could read musical notes as well as ever. This is the converse of the condition in which there is loss of visual memory for musical notes, whilst the patient may be able to read words and letters. Professor Edgren of Stockholm has given numerous examples of such cases and I have referred to this in some detail in a previous paper in THE LANCET.[8] This functional independence of the visual memories of musical notes and words is well illustrated by Case 1.

How is it that there are so few recorded cases of these partial forms of word-blindness? I think the reason simply is that the patient is not thoroughly examined by testing his power of reading all the characters and all the languages with which he is familiar. In Case 1, had I contented myself with observing the patient's inability to read English without testing his power to read the other languages with which he was acquainted, I should never have observed the fact that he was able to read Greek. It has been taken for granted that if a patient was unable to read one language he would, therefore, be unable to read any language, and that there was no necessity for applying further tests. In Case 2, had I examined the patient simply with printed characters, I should not have discovered his greater blindness to written characters. These cases conclusively demonstrate the fallacy of such assumptions, and the facts observed are in perfect accord with the view that our past visual impressions are arranged in the visual-memory centre in definite and ordered groups. They also teach that to examine a patient properly for word-blindness it is essential that the patient should be examined as to all the various characters, printed and written, with which he is familiar, and also as to his power of reading all the different languages which he knows.

Another interesting fact is that two of these four cases of word-blindness were associated with right lateral homonymous hemianopsia. In the one case it was temporary but in the other it was permanent.[9] I had already met with a case in which right hemianopsia was present, and in my report of it[10] I have quoted numerous cases where hemianopsia was associated with word-blindness. This frequent association, as I then pointed out, proves that the centres for the visual memory and for the right halves of both visual fields or the paths to them must lie close together, and pathological evidence confirms the inference thus drawn from clinical experience. The association of these two symptoms has a distinct localising significance. It points to a subcortical lesion in the white matter of the left occipital lobe so situated as to cut across the fibres passing from both occipital lobes to the left angular gyrus, and also the optic radiations passing to the left occipital cortex. The four cases are very instructive as bearing upon the prognosis and treatment of cases of word-blindness.

Cases of word-blindness may be divided into two great classes—first, those which recover more or less completely; and, secondly, those in which the loss remains permanent. Of these four cases, in three there was recovery and in one the word-blindness persisted. The course will depend upon whether the centres or the fibres leading to it have been destroyed, in which case the loss will be permanent, or whether its function has only been suspended by its blood-supply being interfered with, either by pressure of a growth or a hæmorrhage, or by occlusion of the cerebral vessel by a thrombus or embolism. In the latter case, where there is no actual destruction of cerebral tissue, a restoration of function is possible if the blood-supply is gradually restored to the centre either by a gradual diminution of pressure—e.g., by the absorption of a hæmorrhage—or by the re-establishment of the blood-supply temporarily checked by the blockage of a blood-vessel.

Cases 1, 2, and 3 afford excellent examples of recovery by gradual restoration of the blood-supply to the visual-memory centre, which had been cut off either by the pressure of a hæmorrhage or blockage of the branch of the middle cerebral which supplies the centre, either by embolism or thrombosis. Case 3 affords an example, also, of permanent loss of function from destruction of tissue. After recovering the power of reading temporarily lost after the first attack the patient had a second cerebral attack which left behind permanent word-blindness. Both attacks were probably cerebral hæmorrhages, the first attack only temporarily compressing the cortical centre, but the second destroying the cortical tissue, and hence the permanent word-blindness after the second attack. In Case 4, also, the permanence of the word-blindness and of the homonymous hemianopsia points to destruction of tissue, probably by a subcortical hæmorrhage in the region previously indicated.

At the outset of an attack, however, of word-blindness one cannot say with any degree of certainty whether a particular case will recover or whether the loss will be permanent, and hence our prognosis as to the patient recovering the power of reading must be very uncertain. Time alone will show whether there has been actual destruction of cerebral tissue or only temporary suppression of function. If the function is going to be restored, however, signs of improvement will speedily be manifested. The improvement is, as a rule, only very slow and gradual, and in the three cases reported it was three or four months before these patients were able to read with any degree of fluency. The signs of returning function, however, are usually seen within two or three weeks of the original loss. If the patient, as in Case 4, shows no improvement after a lapse of 14 months we may be quite certain that the cerebral tissue has been destroyed and that the loss is permanent. What course should be followed in dealing with these cases?

If you find that the function is gradually returning and the patient is gradually regaining the power of reading then do not try to force it or to accelerate it by asking the patient to practise for so long every day. On the contrary, I always give instructions that such patients are not to be allowed to try to read unless on the occasions that they are tested by the physician. Complete cerebral rest gives the best chance of recovery to the damaged brain tissue. Besides, the possibility of relapse is always to be borne in mind. One of my cases (Case 3) exemplifies this in a very marked degree. This patient had completely recovered the power of reading, which he again completely lost in about seven months after his first attack, no doubt due to a recurrence of cerebral hæmorrhage. Many of these cases which recover are due to cerebral hæmorrhage, and we must ever bear in mind the danger of recurrence. Hence the importance of urging complete cerebral rest in such cases and above all of preventing the patient from practising reading for at least a considerable time after the attack.

Of course, all medicinal measures will be employed with a view to helping the restoration of the cerebral function. If there has been any taint of syphilis, anti-syphilitic treatment must be energetically pushed. Syphilitic disease of the cerebral vessels is the primary cause of the lesion in a considerable number of these cases. In some cases you may get a distinct history of syphilis or manifest traces of past syphilitic lesion may still be present on the body and thus lead to the positive diagnosis of specific taint. But syphilis is such a protean disease that its primary and secondary manifestations are often so slight and insignificant as not to have been observed by the patient, so that even with perfect candour and good faith on the part of the patient no specific history can be obtained. Yet we know from clinical experience that in such cases, where the early symptoms have previous 24 hours. The blood examined showed about 8000 leucocytes—about the same number as two days before. There was no anæsthesia anywhere. The projection over the left frontal eminence was still present and was distinctly painful and pitted on pressure. Percussing over the region with the finger caused wincing, but there was no other painful part of the skull. Ophthalmoscopic examination showed no neuritis, the right disc showed some blurring of the edges, and there was some dilatation of the veins in the fundus.

[10] THE LANCET, Dec. 21st, 1895, p. 1564.

Operation was performed on Oct. 15th at 10 P.M.; chloroform was administered and Mr. Miles operated. A horse-shoe shaped incision was made with its base over the left eyebrow. On reflecting the scalp—which was slightly œdematous—a small area of caries was exposed on the surface of the frontal eminence. It was not larger than a threepenny-piece and only affected the most superficial layer of the outer table. A small quantity of cheesy débris lay between the carious bone and the scalp. A circle of bone which included the carious area was removed with a one-inch trephine. The inner aspect of the bone was normal. The dura mater was *not adherent*, but was slightly thickened. It bulged into the trephine opening and gave evidence of considerable intracranial tension. On incising the dura mater the brain substance appeared to be normal, but it did not pulsate. On introducing the finger a firm nodular mass could be detected occupying the tip of the frontal lobe. The trephine opening was enlarged by rongeur forceps. The tumour was then recognised to be definitely circumscribed and to have a thin covering of cortex over it. To the finger it had the consistence of a normal prostate as felt per rectum. It was easily shelled out without causing any hæmorrhage. The brain pulsated freely as soon as the tumour was removed, and the cavity in the frontal lobe was immediately filled by the brain matter bulging into it. The wound was closed, a small strand of iodoform gauze being left in as a drain at one corner. After removal the tumour was found to be evenly lobulated, having a shape which suggested a comparison to a tomato. It was uniformly firm, of a dull grey colour, and apparently not very vascular. It measured two inches long, by one and a half inches broad and one and a quarter inches in thickness. The microscopic examination, made by Dr. T. Shennan, showed it to be composed *externally of young connective tissue, which towards* the centre gradually passed into caseous material like that found in syphilitic conditions. It was therefore a syphiloma. Next day (the 16th), although somewhat dull, he was able to answer questions. He knew that he was in hospital and he recognised his wife. The following day on the house surgeon going into the ward the patient said, "Good morning, doctor," before the house surgeon reached his bedside. He spoke voluntarily and answered questions in a bright and lively manner—in fact, it was thought that he did so a little too promptly. His condition suggested that of a man who had had a little too much alcohol. He did not wait to be spoken to or asked a question, he started the conversation on his own account. The slight paresis of his *face* was gradually passing off. On the second day he voluntarily controlled his bladder and bowels and asked for the bed-pan when he required it. He had no discomfort in the head. On the 18th he resembled still more a man slightly intoxicated, began to use bad language, and became emotional. On the 21st the patient was still emotional. He remembered events that happened some time before his admission to hospital, but not those immediately preceding. *He did not remember coming* to hospital. *He asked about* the yacht-race—an event in which he had been pecuniarily interested and which had been attracting much attention for a few weeks previously. On the 28th and 29th he complained of pain in his head. The pain was over the seat of the wound, but there was nothing made out to cause it. Iodide of potassium was prescribed. He was able to be up on Nov. 12th and has continued well ever since; he was shown at the meeting of the Edinburgh Medico Chirurgical Society on Dec. 4th, 1901.

The chief points that enabled us to arrive at a diagnosis as to the localisation of the lesion that produced the symptoms in the patient may be summarised as follows. The symptoms undoubtedly pointed to the cerebrum rather than to any other part of the nervous system. The only symptom which might have caused confusion was the apparent want of control over his bladder and rectum. Careful inquiry, however, showed that the loss of control had a higher origin than the spinal cord—that, in fact, we had to do with a case in which as far as these functions were concerned the man had been reduced to the animal condition as in advanced dementia. Associated with this symptom was that of loss of modesty and shame, just as one finds in cases of dementia, where there is a gradual involution of the nervous system beginning in the higher levels. The general condition of the patient and the short duration of the illness enabled us, however, to *exclude dementia. It was not quite so easy to exclude* cerebral softening due to embolism or thrombosis, but the history of the case—viz., the gradual onset of the symptoms (there being no history of a sudden attack and especially no history of distinct paralysis of motion or sensation either general or of the special senses)—pointed to the softening, if present, being in the frontal region and not in any area further back. Cerebral thrombosis or embolism, however, is very rarely limited to the frontal region and is very much more common in the central regions of the brain—i.e., in the areas supplied by the middle cerebral and its terminal branches in the Sylvian fissure. Hæmorrhage was excluded for almost the same reasons as were embolism and thrombosis, *but especially from the history of the gradual onset, although* it was necessary to bear in mind that the rapid increase in the severity of the symptoms the day before the operation might have been due to hæmorrhage from a previously existing tumour. This rapid progress, however, was thought to be more probably due to congestion and œdema—a condition which frequently comes on where there is a tumour and often leads to a suddenly fatal issue. Abscess was excluded from the history and from the absence of fever and of leucocytosis.

The symptoms which pointed to tumour were—the gradual onset and the apparent steady increase and progress of the symptoms from the time that the patient gave up work about a month before admission. These symptoms indicated a gradual increase of intracranial tension. The slow and dull cerebration with depression of spirits, together with the slowness of the pulse and the attacks of vomiting without apparent cause, were very suggestive of increased intracranial tension. The usual eye symptoms were absent, but unfortunately only one eye could be examined, and that the one on the opposite side from the lesion. His good eye, although it had no optic neuritis, showed blurring of the *edges of the disc with some dilatation of the veins.* A tumour being indicated, was there anything pointing to its seat? In the first place, we had a symptom which pointed to a lesion of the left side of the brain—viz., the very slight paresis of the right arm, the more distinct paresis of the right side of the lower part of the face, with dysarthria in speaking, but no aphasia. The symptom pointed to an implication of the fibres passing from the lower part of the Rolandic areas to the internal capsule. The fact that there was no aphasia showed *that Broca's convolution was not affected*, and as there was much less affection of the arm than of the face the lesion producing this symptom was almost certainly in the centrum ovale subcortical to the lower part of the Rolandic areas. One other symptom pointed to the left side of the cerebrum. There was a slight but distinct swelling over the left frontal eminence which was painful to pressure and was slightly soft in the centre. This was felt to be distinctly external to the bone, but as he had a cicatrix over the other side of his forehead where he had had a previous swelling three years before which had been incised, the present one was looked on as specific in character and therefore might be associated with a gumma on the internal *surface of the skull.* These two *symptoms, therefore*—viz., the presence of the paresis of the right side of the face and the presence of a swelling over the left frontal region—apart altogether from his mental symptoms, pointed to the tumour being on the left side. His mental or psychical symptoms were, however, not only confirmatory, but if they had been taken alone would have been sufficient to have justified an operation over the left frontal region. These symptoms may all be considered as a loss or depression of the *inhibitory* power of the individual. Such *symptoms* are exceedingly difficult to analyse and are even more difficult to describe. The absence of such symptoms renders a man what he is, gives a man his distinctive character in relation both to the lower creation and to his fellow-men—the presence of such symptoms alters the *ego* of a man, takes away his special mental characteristics, and reduces him to a lower level. The loss of inhibition of his organic centres, such as those of the bladder and rectum, we help in locating the tumour, but there are still many "latent" or "silent" regions of the brain, lesions in which give rise to no symptoms or to symptoms which are as yet not understood.

Our patient suffered from a tumour of one of those so-called "silent" regions—viz., the left prefrontal lobe—and his case illustrates the fact, which has been pointed out by *several* observers, that a tumour or other lesion in this region gives rise to a fairly definite group of symptoms. The prefrontal lobe was looked upon as a silent region from the fact that experiments—such as those of Ferrier, Horsley, and others—failed to elicit any definite motor reaction when this part of the brain was electrically stimulated. Extirpation of the prefrontal lobes in monkeys, however, gave rise to a train of symptoms which, as far as they can be compared, closely resemble those exhibited by our patient as well as by the patients in other reported cases. As these symptoms are produced by an interference with inhibition, with attention, and with judgment, which are probably the highest functions of the brain, rendering man pre-eminent amongst living creatures, it is very difficult to compare such symptoms with those exhibited by the lower animals.

Our patient, a man, aged 47 years, was admitted into Leith Hospital on Oct. 12th, 1901. The history we obtained was that he had enjoyed good health till the May before his admission when he began to suffer from pain in the back of his head and in the small of the back and shooting pains in the legs. Soon afterwards the pain was referred to the left frontal region and it subsequently remained localised to that part of the head. Early in his illness the left side of his forehead and face became swollen to such an extent that his left eye was closed, and while this swelling lasted the pain in the head was relieved. After about four weeks the swelling began to disappear gradually. During this time the patient was taking some medicine—probably potassium iodide—which had been prescribed for him previously at the Royal Infirmary, Edinburgh. He had occasional attacks of vomiting of the cerebral type, without relation to food or other apparent cause. He continued at his work till Sept. 12th, on which date the term of his employment expired. For about a fortnight he was no worse, but then he became depressed, refused to leave his bed, and would not speak to his wife. He sometimes refused to take his food, although his appetite appeared to be normal. His memory became affected also, so that he would forget in a few minutes what he had been saying. He became very emotional and would begin to weep at the sight of his friends—as his wife expressed it, "he became kind o' soft." It was also a source of annoyance to his friends that he seemed to lose all sense of decency and shame and exposed his person unduly and needlessly. He suffered from incon- ce of urine but had full control over his rectum. At he appeared not to be aware where he was, and when own house he would say to his wife, "Let us get away ere." During the night especially he seemed to lose arings and did not know where he was. At this time plained greatly of the pain in the left frontal region a swelling appeared over the frontal eminence. All symptoms gradually got worse and he was sent to Leith ospital on Oct. 12th, 1901.

On admission the patient lay on his back in apparent comfort. He was sleepy, dull, and apathetic, and could only be roused with difficulty by pinching or shaking him or by a sharp question. When awakened he yawned frequently. His hearing seemed to be normal. His responses to questions were correctly expressed, but were made more slowly than was normal. He could not sustain his attention for any length of time; any subject which was brought before him, although it might attract his attention for a moment, seemed to pass from his mind very soon. As regards the affection of his memory, it appeared to be not so much a blotting-out of his past impressions as a want of power of associating memories, of comparing and contrasting them. Lack of judgment, therefore, was a marked feature of his mental condition. There was no aphasia, but there was some degree of dysarthria which was well marked on his attempting to pronounce test words and sentences, such as "British Constitution," "truly rural," and "artillery." His reading and writing could not be tested as he had never learned to read and to write. There was paresis, especially in the lower part of the right side of his face, and the power in the right arm, as evidenced by the grasp of the hand, was not as great as in the left side. He complained of occasional pains, which were not very severe, shooting down the front of both legs. The plantar and patellar reflexes were present but not exaggerated. There was ankle clonus. He seemed to walk easily and, as far as could be tested, his coördination was not impaired. His wife stated that he had staggered on suddenly getting up out of bed, but he did not complain of giddiness. There was no pain in the left frontal region unless when the skull was percussed. An examination of the blood showed hæmoglobin 90 per cent., red blood corpuscles 4,800,000 and white corpuscles 8000. On microscopic examination of films nothing abnormal was detected. The sight of the left eye was completely lost, the eye having been disorganised by small-pox 25 years ago. The sight of the right eye was still good. The right pupil was slightly contracted but responded to light. Although the patient saw quite well he was not accurate in counting the number of finger held up before him. He could name objects at sight quite well. He could not tell the time on a watch correctly although he recognised that it was a watch and said so whe asked to name it. He had no difficulty in recalling words or names. He answered questions slowly and apathetically and in such a way as to indicate that he took no interest in what he was saying. His gestures also suggested this. For example, if he was shown a watch and asked what it was he looked at it and said "A watch." Then he half closed his eyes, assumed a disinterested expression, and turned his head away as if he had completed some piece of work and was now done with it. When asked his name he gave it all right, but when asked his age he said, "Sixteen." On being asked the same question repeatedly he always answered "Sixteen." He was then asked if he was a hundred and he answered, "Yes, more than a hundred." When asked where he lived he gave the name of a street he lived in a few years previously. On being asked if he lived in S—— street (where he really did live) he said, "Yes." When asked, "Where are you living now?" he said, "Here." Over the left frontal eminence was a small round swelling evidently arising from the bone, in the centre of which was a soft area. It was tender on pressure. Over the right frontal region was a small depressed cicatrix the result of an abscess which had been opened three years previously in the Royal Infirmary. The tongue was slightly tremulous and flabby, moist, and very slightly coated posteriorly. It was protruded in a straight line. The teeth were bad, the breath was foul, and the bowels were regular. The abdomen was slightly tympanitic. There was no splenic or hepatic enlargement. He passed his urine and fæces in bed, but this apparently was not from want of control of his sphincters but from want of appreciation of the impropriety of doing so.

As regards the history of the patient previously to the onset of his present illness it was stated that he had always enjoyed good health. Syphilis was denied. He had been married 17 years and his wife had had three miscarriages—at six, seven, and eight months respectively—and four living children. Three years before he had had "an abscess" opened over the right frontal region. Four years before this abscess formed he had received a blow on that region. There was no history of injury to the left side of the head. He had never been a heavy drinker or smoker.

With regard to the treatment and progress, on admission on Oct. 12th the patient was put on light diet and given iodide of potassium and mercury. On the 14th he was very drowsy and was much more stupid. He would not speak and there was great difficulty in making him take food. He evidently did not realise where he was. He vomited once after dinner. There were aimless movements of his hands. At 7.30 P.M. the patient exhibited a constant up-and-down movement of the left arm which was not purposive. There was no twitching of the muscles. He could move his legs freely and equally well, but kept his right arm still unless a stimulus sufficiently strong to be painful was applied. On the morning of the 15th he was much more stupid—could hardly be roused and could not be made to answer except by a grunt or monosyllabic sound. His breathing was sometimes almost stertorous and had a tendency towards the Cheyne-Stokes type. There was slight rigidity of the right arm. On pinching his face he carried both hands up to the painful part. He was in much the same condition up to 8.30 P.M., when it was noticed that he had slight difficulty in swallowing and that his breathing had become more Cheyne-Stokes-like. His pulse since admission had been slow, ranging between 60 and 68. The temperature was normal but had shown a tendency to rise to about 99 during the

I found the patient sitting up in bed, leaning forward with her head almost touching her knees, which were raised up, suffering from most terrible dyspnœa. Her face was livid; she was bathed in cold sweat; her breathing came in short, sharp gasps; and with each expiration she ejected, without any apparent effort, a thin pinkish fluid. She was apparently dying. The remedies which I then applied were an injection of one ounce of brandy with gruel into the rectum—she was far too distressed to swallow anything—the application of hot-water bottles to her feet, and the free application of very hot fomentations to the præcordium. The pulse was small and very rapid, the respirations were from 30 to 40 per minute, and the temperature was normal. Loud moist sounds were heard all over the chest. The amount of expectoration was very great. After four or five hours there was some improvement in her condition and she was able to swallow. I administered at intervals of 15 minutes two drachms of sweet nitre diluted with water. She was apparently very much relieved after three doses of this remedy. On the following day she seemed to be little the worse for the attack with the exception of being languid and tired and disinclined for exertion. I prescribed rest in bed for a day or two and gave her a mixture containing bromide of potassium and camphor. I ceased attendance on the third day as she seemed to be all right. The urine was not examined. Four days afterwards, on July 3rd, I was hurriedly sent for about the same time in the evening, and there was a repetition of the above-described condition, with the same result. After this second attack I made a very thorough examination of the patient, but could find no organic trouble of any kind. The urine on this occasion was not examined, but I gave directions that a sample should be retained every day, and that if the attack recurred the sample of urine passed immediately before the attack should be sent to me. On July 30th the patient had a third attack, and the urine was examined, but nothing abnormal was detected in it. She had 20 attacks in the next 12 months. In the meantime I looked up the subject in the literature at my disposal, but could find no description of any case exactly like that of my patient. I discussed it with various medical friends who could throw no light on the subject. I looked upon the case as one of asthma in a wide sense of the term, but such remedies as stramonium in its various forms, arsenic, belladonna, digitalis, and stimulants appeared to me to do harm rather than good. The attacks became so frequent—they seemed to have become a habit—and they were so terrible to witness that I was in despair over the case, for by now my patient was a confirmed invalid, unable to do any household work, and was completely broken down by the frequent attacks, and possibly in some degree by the drugging which I had subjected her to, in the vain hope of finding a remedy.

In March last I made up my mind that I would treat the next attack with chloroform, having already tried nitrite of amyl with unsatisfactory results.

I commenced the administration of chloroform in fear and trembling as to the result. I administered it in the ordinary way on a handkerchief, giving the patient a whiff of chloroform and a breath of air in alternate inspirations. The gasping, short nature of the breathing, and the obvious obstruction due to the frothy material in the air-passages prevented any great amount of chloroform vapour being introduced into the lungs. However, after from 10 to 30 minutes of administration in this way a marvellous change came over the patient. The lividity disappeared, the breathing became easier, the action of the heart became far less laboured, and the respirations slowed down, the patient lying back on the pillows apparently asleep. This condition lasted perhaps for an hour, when I roused her, and she expressed herself as feeling all right. So striking was the relief afforded that my patient begged me to leave the remedy with her in future, so that she could administer it to herself in case of need. I would not consent to this at that time, as I feared that carelessness in giving the vapour in too concentrated a form might end in disaster. During the next three months she had 23 attacks, at each of which I administered chloroform, with the invariable result that the attack was stopped in from 20 to 30 minutes. I was away from home last June for three weeks. My locum-tenent was called to the case, but he declined to take the responsibility of giving chloroform without a consultation. A consultation was held and the husband was informed that his wife was dying and that the administration of chloroform was out of the question, so my patient endured six or eight hours of her previous agony. Fortunately I was at home when the next attack occurred, and I was able to convince my colleagues of the value of the remedy. So terrified was my patient at the idea that I might not be available at any future attack that she begged me to teach her husband how to administer the remedy, and I, having lost all fear of any ill-effect from the judicious administration of chloroform in her case, devised the following method for her husband to carry out. I gave him two drachms of chloroform with instructions to put in an ordinary tumbler a few square inches of clean blotting-paper, to pour the chloroform on the blotting-paper, and to hold the tumbler upright under the patient's mouth and nose, but to be very careful that she did not take more than three inspirations from the tumbler without one intervening inspiration with it away. I witnessed the management of the chloroform on several occasions, and now he habitually gives the remedy, but I never allow him to have more than two drachms of chloroform in his possession at any one time. The attacks now, from beginning to end, with the administration of chloroform at the earliest possible moment, rarely last half an hour, and my patient appears none the worse the day following them. She has had no medicine for many months. I have notes of 72 attacks in the two and a half years during which she has been under my care and they were all as instantaneous in their onset as an epileptic fit. They varied somewhat in intensity and duration from time to time, but they were all characterised by these constant phenomena: suddenness of onset, intense agonising pain in the chest, frightful dyspnœa, lividity of the face, profuse cold sweat all over the body, laboured action of the heart, with a small rapid pulse, and, lastly, but most important, the ejection (one can hardly call it expectoration, for that implies coughing, which is almost absent) of enormous quantities of thin pink, sero-mucous fluid. I have measured as much as 42 ounces of this fluid in an attack lasting eight hours. I have never detected rise of temperature in the rectum or vagina during an attack. The attacks always occur at night. They are almost invariably preceded by a desire to go to stool and the dyspnœa always comes on then during the act of defecation. They very often occur about the period of menstruation, especially if that is delayed a few days, as it often is, though it is normal in other respects. I saw my patient to-day (Jan. 12th, 1902). She says she is better in every way than she has been for years. She is no longer an invalid, she is cheerful and confident, and can do her work as well as ever she did. I could find no organic disease of any kind. The urine is not albuminous. She has lost all fear of the attacks provided she has the chloroform at hand and she tells me that five minutes is now about the time the distress lasts, and then "everything eases off." She often does not go to sleep from the effects of the chloroform, but the attack never returns that night. There has been no pinkish sputum for some months. She is getting rid of the habit. I can add nothing further to the admirable description of these attacks given by Dr. Steven, but I have a word to say in regard to the pathology. The symptoms appear to me to indicate clearly obstruction in some part of the pulmonary circulation. The hypothesis which I have formed is this. Owing to some cause—at the nature of which I do not even guess—it seems to me that there is a spasm of the pulmonary venous (or efferent) system. This will account for the rapid engorgement of the lung and the consequent extravasation of serous exudation in the alveoli, just as engorgement occurs in a limb in venous obstruction. Spasm of the efferent vessels *alone* would allow rapid accumulation of blood in the (afferent) pulmonary artery and its branches, and the terrific labour of the heart which is present appears to be an effort to overcome this obstruction. The continued obstruction would eventually lead to general systemic venous engorgement, hence the lividity of the face, &c. The action of chloroform in my case seems to bear out my hypothesis, for as soon as the centres which preside over this spasm are affected by the chloroform the whole train of phenomena subsides. On the contrary, if the attack is allowed to run its course, it seems to me that the centres eventually become so paralysed by the effect of the carbonised blood that the same result happens. The spasm is relaxed eventually and the symptoms disappear but in hours instead of minutes, as they do under the action of chloroform.

Acute spasmodic asthma, which resembles this condition in many respects, differs, as Dr. Steven points have already referred to. His emotional condition was a prominent symptom in his case. The loss of his sense of modesty and shame we have also alluded to. These quite evidently point to loss of inhibition and are important symptoms in pre-frontal lesions. But to many the loss or diminution of the faculty of attention—the most prominent symptom in his case—will not so evidently appear as a loss of inhibition. Yet so it is; there can be little doubt that attention is largely an inhibitory process—in fact, some psychologists consider it entirely so. Be that as it may, a want of the power of attention was a marked feature in this case. His attention could be directed for a second to any object or statement, but only for a second. The next second he was apathetic and listless and required to be again roused. Closely allied to this loss of attention was his loss of power of forming a judgment about anything. He could not compare or contrast two things or ideas. This again may have been due to his want of power of sustained attention, his not being able to have two ideas in his mind at one time. His individual memories seemed all right. He saw objects, knew what they were for, and could name them all right. Whilst his memory for objects and things that he had seen before his illness was unimpaired, his memory for things that were shown him and events that happened since the onset of his most marked symptoms was very imperfect. He forgot what happened almost immediately. This probably in part resulted from the diminution in his power of sustained attention and in part from the general depression of the cerebrum due to the intracranial pressure, so that recent memories did not become fixed, because fixation in memory requires health and nutrition. This is proved by the fact that even now when he has recovered he has not regained the memory of events that happened for some time before his admission to hospital. It is questionable whether the prefrontal lobe has anything specially to do with the fixation in the memory apart from the faculty of attention—although the process of voluntary recollection is probably initiated in the prefrontal lobe. The symptoms exhibited by this patient have been pointed out as occurring in prefrontal lesions and there are now a good many such cases in medical literature. The time has come when we should discard the idea that the prefrontal lobes are "silent regions." Far from being silent regions, the left prefrontal at least speaks in decided if little understood language as being the seat of faculties the loss or deterioration of which completely changes the character of a man. There is much evidence to show that the left prefrontal, just as the left Broca's convolution, takes a more prominent part in higher cerebration than the right prefrontal, but into this question we have no intention of entering at present. The best summary of the symptoms of pre-frontal tumours which we can find in medical literature is that of Allen Starr of New York who along with McBurney[2] in 1893 described a case very similar to ours in which a sarcoma was removed from the frontal lobe. The position of the tumour was, however, somewhat further back than in our case, and therefore produced more symptoms pointing to the motor areas. Starr[3] had in 1884 made an inquiry into the symptoms of 23 cases of disease of the frontal lobes and found that decided mental disturbances occurred in half of them. The following were his conclusions: "The form of mental disturbance in lesions of the frontal region does not conform to any type of insanity. It is rather to be described as a loss of self-control and a subsequent change of character. The mind exercises a constant inhibitory influence upon all action, physical and mental, from the simple restraint on the lower reflexes, such as the action of the sphincters, to the higher control over the complex reflexes such as emotional impulses and their manifestation in speech and expression. This action of control implies a recognition of the import of an act in connexion with other acts—in a word, it involves judgment and reason, the highest mental qualities. By inhibiting all but one set of impulses it enables one to fix the attention upon a subject and to hold it there. It seems probable that the processes involved in judgment and reason have for their physical basis the frontal lobes, if so, the total destruction of these lobes would reduce man to the state of an idiot, while their partial destruction would be manifested by errors of judgment and reason of a striking character. One of the first manifestations would be a lack of that self-control which is the constant accompaniment of mental action and which would be shown by an inability to fix the attention, to follow a continuous train of thought, or to conduct intellectual processes. It is this very symptom that was present in one half of the cases collected. It occurred in all forms of lesions—from injury by foreign bodies, from destruction by abscess, from compression and softening due to the pressure of tumours—and therefore cannot be ascribed to any one form of disease. It did not occur in lesions of other parts of the brain here cited. But its presence in such a large number of these cases warrants the suggestion that in cases of suspected lesion of the frontal lobe the mental condition of the patient as shown by his acts of judgment and reason should be carefully examined and a change of character or behaviour carefully noted." It would be impossible for us to wish to have a better description of the symptoms of our case than this of Starr, the result of an investigation into the symptoms of frontal lesions. Ferrier,[4] Welt,[5] Gilman Thompson,[6] Griffith and Sheldon[7] as well as other neurologists and psychologists have produced evidence more or less in favour of these conclusions. We would point out one other symptom in this case which has also been pointed out by Bruns[8] as occurring in cases of frontal tumour—viz., staggering on walking or attempting to walk. Our patient had this symptom and Bruns points out that it may suggest cerebellar disease. He says that the symptom is usually absent in tumours of the Rolandic areas. It has been suggested that the symptom may arise from involvement of the bundle of fibres which are known to pass from the frontal lobe to the cerebellum. The same bundle may explain the fact that our patient at the beginning of his illness had an intense pain in the back of the head which, however, gradually passed round to the frontal region. It is interesting to note the symptom in connexion with the opposite condition which has been pointed out by Dr. Purves Stewart, that cerebellar lesions may be accompanied by frontal pain.

The removal of the tumour was followed by a rapid disappearance of the dull and depressed symptoms in this case, and the only mental symptom that has been noticed since is what one would describe as good cerebration evidenced by slight "forwardness" and sometimes "witticism." Oppenheim and Jastrowitz have pointed out that "hilarity" and "witticism" are accompaniments of frontal tumour, but we would suggest probably only before intracranial pressure gets too great. These symptoms are probably explained by slight injury to some of the structures concerned in voluntary inhibition. The condition is allied to that seen after administration of a moderate amount of alcohol, the result of the alcohol being, according to some authorities, the reduction of inhibitory control. It is a curious fact that the affection which produced the swelling over the frontal bone was not structurally connected with the tumour in the frontal lobe. That tumour had begun at the anterior part of the lobe and had extended backwards and downwards, pushing the structures before it, until latterly it had implicated the fibres passing from the lower Rolandic areas to the internal capsule, so producing the paresis of the right side of the face and of the arm.

# ACUTE SUFFOCATIVE PULMONARY ŒDEMA.

BY THOMAS LISSAMAN, M.R.C.S. ENG., L.R.C.P. LOND.

I HAVE read with the greatest possible interest the very full and graphic description of this condition by Dr. J. L. Steven in THE LANCET of Jan. 11th, p. 73.

I am fortunate, or unfortunate, as the case may be, to have under my care a patient who has suffered from this affection for two and a half years. She is a married woman, aged 45 years, with five children. She is stout and well nourished, with no traces, as far as I have observed, of any organic lesion of the heart, kidneys, or lungs, or, indeed, of any organ. She first came under my notice in June, 1899.

an hour after returning to bed he complained of feeling very ill and faint. Subcutaneous injections were again administered in order to restore the failing heart, but this time the patient died. A necropsy could not be obtained until 36 hours after death, when the brain presented a congested appearance and there was evidence of minute subpial hæmorrhages. The meninges showed no signs of inflammation. Some of the cerebro-spinal fluid was collected in a sterilised bottle, from which cultures of the diplococcus lanceolatus were obtained. Nissl sections of the brain were made later under the direction of Dr. F. W. Mott, but no pathological changes in the cortical cells could be discovered. The other organs were normal.

Acute delirium is generally regarded as the most convenient term to apply to a somewhat rare but fatal group of clinical cases of which the two narrated above are types and which seem to be worthy of record. In all, practically, there is a predisposition to mental instability, hereditary or acquired. Some observers, especially in Italy, have described a bacillus associated with this condition, and others have found various kinds of cocci, whilst in many cases no organisms can be found at all. It seems probable that the toxins arise autogenetically.

Upper Berkeley-street, W.

# THE DECAY OF AUSCULTATION AND THE USE OF THE BINAURAL STETHOSCOPE.

By H. W. SYERS, M.A., M.D. CANTAB.,

*PHYSICIAN TO OUT-PATIENTS, GREAT NORTHERN CENTRAL HOSPITAL.*

THE student of the present time is in danger of being overwhelmed by the multiplicity of the methods of diagnosing and treating disease. The continual outpouring of new remedies, most of which soon pass into merited oblivion, and the incessant recommendation of new (very often ancient) modes of treatment, chiefly distinguished by their grotesqueness, with all of which he is credited with possessing some sort of knowledge, render his career in the domain of therapeutics a chequered one. But with this side of the question I have now no concern, intending, as I do, to deal only with the method of diagnosis.

Twenty years ago the student was taught to rely almost entirely on the results obtained from the employment of his unaided senses, from the aspect of the patient, his attitude, and his mode of answering questions; in all these ways it was necessary for the learner to draw his own inferences, the use of special instruments being confined to that of the microscope, stethoscope, laryngoscope, and ophthalmoscope. Now, owing to the introduction of complicated blood examinations, of bacteriological methods of diagnosis, of colour reactions with the urine, and of many other proceedings of kindred nature, so much time has to be devoted to special modes of research that there is real danger of the old-fashioned but well-tried methods being relegated to the background in the student's scheme of practical work. To this craze for the employment of laboratory tests and for short cuts to diagnosis I attribute much of the present-day weakness in bedside examination which is, I regret to say, so often in evidence in union with the possession of the highest medical qualifications. These remarks are quite general and apply to no mode of examination in particular.

But, to pass from the abstract to the concrete, I would draw attention to a most urgently required reformation in a very important method of examination, an examination which is undertaken daily and hourly and which lies at the very foundation of clinical work. I refer to the examination of the chest and to the manner in which it is carried out. Until about 20 years ago the condition of the thoracic organs was always investigated by means of the wooden stethoscope, an instrument now almost banished and rarely seen either in hospitals or consulting-rooms. At the time referred to it became the fashion to employ the binaural instrument, at first in quite a tentative manner, then in combination with the use of the wooden instrument, and finally boldly and openly as the only stethoscope worthy the name. Now, were it the fact that the binaural instrument possessed advantages rendering it greatly superior to the wooden one this supersession of the latter would be merely an ordinary instance of the survival of the fittest, and nothing would remain to be said on the use of stethoscopes. But the facts are altogether opposed to this view of the case, and I am convinced that much of the faulty diagnosis of chest disease which is so frequently seen at the present day is the result of the habitual use of the binaural stethoscope. And the reason why this important matter has not attracted attention hitherto is, I have no doubt, the undue weight which is attached to those laboratory methods of diagnosis to which I have already alluded, and which can only result in the production of an unsound, unpractical, theoretical (in the worst sense of the term) type of clinician. The errors which are the direct and immediate result of the constant use of the double stethoscope are of course most obvious in the case of those whose experience of the physical evidence of disease is limited, and is less apparent when the examiner by long practice has become familiar with the physiognomy of disease, so that he is to a great extent free from the necessity of employing an instrument in order to draw his conclusions as to the nature of the illness. But even in this case errors of omission, though not perhaps of commission, are not seldom made through the employment of the binaural stethoscope, while in the hands of the younger brethren faults of both kinds are, to my certain knowledge, only too frequently committed, due entirely to the obstinate use of this most pernicious instrument.

I will now in a few words give my personal experiences in this important matter of diagnosis by means of the ever-popular binaural stethoscope. I have convinced myself that as regards the investigation of the sounds of the heart this instrument is most unreliable, and increasing experience, not only of students' work, but of that of qualified practitioners who are in the habit of employing the double stethoscope, confirms me in the opinion that unless the use of this instrument be discontinued in no long time aortic regurgitation at all events will be a disease which cannot be certainly diagnosed. I do not, of course, refer to those cases in which the diastolic aortic murmur is so obvious that it cannot possibly be mistaken, but to that very large class of murmurs due to incompetent aortic valves in which the bruit is soft, low-pitched, and not by any means easy to hear. It is these murmurs which are constantly passed over, the second sound being described as "clear." The least reflection will convince anyone of the great danger attending the failure to discover such a murmur. In the case of a candidate for insurance much injury may be done to the office and one of which the directors would have every right to complain. It is well known that the soft, low-toned regurgitant murmurs are just those which are found in cases subsequently dying suddenly, the very softness of the murmur being a most unfavourable indication as depending upon a feeble ventricular systole. But it may be urged that in aortic disease the physical signs, apart altogether from the murmur, are so characteristic that it would be impossible for the lesion to be overlooked. I would reply to this objection that in the case of the murmur in question the left ventricle is often scarcely at all hypertrophied, there is no throbbing of the carotids, and the radial pulse may not possess the characters associated with the presence of aortic reflux. As regards the latter, indeed, the qualities of the pulse found in aortic regurgitation are by no means seldom met with in people whose aortic valves are perfectly healthy. It may also be mentioned that even if hypertrophy is present it is often masked by emphysema.

Thus, then, we are reduced to the evidence furnished by the murmur and this alone, in forming the diagnosis of a most serious and fatal form of cardiac valve lesion, and it is neither more nor less than a calamity for such a murmur to be overlooked. Yet to my certain knowledge this happens every day. Now, a murmur may be passed over from the incompetence of the examiner as well as from the unsuitableness of his instrument. In other words, it may be in some cases that a bad workman unfairly complains of his tools. But this argument, in my experience, does not apply to the question now under consideration. Most efficient and even brilliant auscultators I have found to overlook constantly this variety of murmur simply and solely because the binaural stethoscope which they to their subsequent sorrow, had been in the habit of using had misled them. The same observers when immediately afterwards employing a wooden stethoscope have invariably detected the murmur at once and have acknowledged their error, attributing it to its rightful cause—the use of an untrustworthy instrument. This is a certain proof that the slip was the out, in the absence of the peculiar whitish-pink, abundant expectoration. It seems to me that the difference in the two conditions may lie in this—that in acute spasmodic asthma it is the pulmonary artery, or afferent system, that suffers from spasm, and in acute suffocative pulmonary œdema, it is the pulmonary vein, or efferent system, which is affected; for in the former case there is anæmia of the lungs with no expectoration during the attack, and in the latter there is engorgement, with pints of it. In other words, in acute spasmodic asthma ("dry asthma") the lungs are in much the same condition as the fingers are when they are cold, white, and "asleep," or as in Raynaud's disease. In acute suffocative pulmonary œdema ("wet asthma") they are, perhaps, in a similar condition to the extremities in certain forms of erythromelalgia. I think, therefore, one may reasonably argue that the two diseases are similar, but that they differ in the site affected by the provocative agent, whatever it may be. Both clinical pictures may be ascribed respectively to vaso-motor spasm of the different pulmonary vascular systems.

I shall certainly rely with confidence upon chloroform as a remedy for both conditions in future, for it seems to me from the observation of my case that great damage was done by sedative drugs and also by stimulation by alcohol, and none of the vaunted remedies for asthma did my patient any good. She seemed to be drifting into a condition of imbecility, like an epileptic does, until the systematic administration of chloroform stopped the violence of the attacks. She still has attacks—about two a month (instead of three or four a week as in March last)—it is true, but as the duration of them is so short and the remedy inspires such confidence she feels sure eventually she will completely recover.

Bolton-le-Moors.

# TWO CASES OF ACUTE DELIRIUM.[1]

BY R. H. COLE, M.D., M.R.C.P. LOND.

CASE 1.—The patient was a single woman, aged 40 years, living with her widowed mother. For the sake of employment and to supplement her income she had lately taken some work. There was no family history of insanity, but both the patient and her mother were decidedly nervous, and a brother had died from hip disease. Until nine months before she came under my observation she had enjoyed fairly good health. She then developed a bad attack of pernicious anæmia, from which, however, she recovered at the end of three months and returned to her work. On Feb. 21st, 1900, she again began to feel ill and prostrate, and she feared a relapse of her former illness. This time, however, she was more nervous and apprehensive, complaining of vague cranial uneasiness, and she said that she felt that she was "going off her head." The blood was examined again; it was found to present signs of pernicious anæmia and she was admitted for treatment into a nursing home. The nervousness and restlessness increased and in a week's time, after a few hours' warning, she became completely delirious which, on March 4th, necessitated her removal to an asylum where she was under the care of Mr. G. E. Mould. Before the delirium developed she had three sleepless nights. The patient now presented a wild appearance; she had no powers of recognition whatever and chattered incessantly, her speech being incoherent and the same phrases being repeated over and over again and she asked questions which she proceeded to answer herself. She gesticulated and was under the influence of visual and aural hallucinations. At times she had an ecstatic expression, apparently believing herself in heaven with angels flitting about. She had to be fed artificially and her bladder and rectum required constant attention. In spite of sedatives it was difficult to procure any sleep. The pulse was weak, varying between 120 and 140, the temperature being 99° F. There were a dry cracked tongue and sordes on the lips. The patient was given abundant nutriment and stimulants but she was evidently becoming exhausted. On the 9th her temperature rose to 105° and she seemed to be in a moribund condition. She was ice-packed, a hypodermic injection of strychnine was administered, and the stimulant (brandy) was increased. She rallied somewhat and the temperature was reduced, only to rise again on the following day to 107°. The patient was then placed in an ice-cold bath for half an hour which reduced the temperature to normal for a few hours. On the temperature rising once more she was placed on an iced water-bed and was given quinine and strychnine by the mouth and meat extracts and stimulants. She responded but feebly to these agents; the delirium had now become of a low muttering form and she picked at the bed-clothes. She died on the 11th in a state of collapse. Unfortunately no post-mortem examination was obtained.

CASE 2.—The patient was a young professional man, aged 27 years and single. An aunt had suffered from chronic insanity. With the exception of an attack of influenza a few years previously the patient had always enjoyed excellent health. He was by nature sociable, athletic, and clever, and had led a regular and temperate life. He was about to begin his life's work, having just finished his final examinations. He seemed unduly to feel the responsibility of his office, and some irritability and change of disposition were observed by his friends for a fortnight or more. On April 3rd, 1901, he first complained of not feeling well, being depressed and unable to collect his thoughts; however, he continued at his work until the 6th, with sleepless nights, when one of his friends gave him a Dover's powder and sent him to bed. On the 7th his manner was so strange that an attendant was engaged. He looked very dejected and would hardly speak; he gave expression, however, to delusions that he had neglected his work and ruined his family and he was somewhat suspicious about his diet. He could obtain no sleep without hypnotics and five days later (on the 12th) he was transferred to an asylum for special treatment. He would not eat an ordinary meal, but after persuasion drank milk on the first two days after his admission. From the 14th to the 21st he had to be fed with a tube (nasal). He was now in an exceedingly resistive mood, champing his teeth, refusing all food, and struggling during the dressing and when undressing or when going out for exercise and returning to his room; he now, however, slept well and without any hypnotics. On the 22nd he took his meals voluntarily, and on the next day he had a lucid interval which commenced suddenly and lasted three hours; during this interval he stated that he had a vague recollection of being moved to the asylum, but could scarcely remember anything more. He gradually became more restless and inattentive, and in the course of an hour he had drifted into a semi-stuporous condition, but he was quite tractable and took his food well. He would not speak except to utter emotional phrases, and any reference to his friends or relatives increased his agitation. In this state he remained for five weeks. On the night of May 28th he was sleepless and he looked ill on the next morning, his temperature being 100° F. and his pulse 120. He became very excited, struggled with his attendants, and took his food only by compulsion. During the next three days the patient was in a condition of acute delirium and evidently under the influence of terrifying hallucinations, chiefly of a visual nature. He occasionally talked, but his speech was incoherent and almost unintelligible. The pyrexia increased to 102°, and his pulse varied from 120 to 150. Sedatives were administered but he obtained very little sleep. From June 2nd to the 8th he lay on a water-bed in a very prostrate condition, with a dry tongue and sordes on his lips, and in order to ensure sufficient nourishment he was again fed by a nasal tube. Six ounces of brandy and four ounces of port wine were now given per diem and sleep was obtained by means of two drachms of paraldehyde every night. His pulse, which had always been rapid, was now intermittent and gave cause for anxiety. On the 5th he had a syncopal attack, but recovered with the assistance of a hypodermic injection of strychnine. The muscular system was in a state of hypertonicity and change of position was accompanied by pain. On the 9th the patient again began to take food voluntarily and seemed to be a little stronger. His temperature on this day was 100° and his pulse was 130. On the 12th the temperature returned to normal although the pulse continued to be rapid. In order to ease his back he was now allowed to sit up for an hour occasionally. Mentally he was still in a state of confusion, but he would answer simple questions and appeared to be slowly recovering. On the 15th he woke up in the middle of the night to use his night-stool, and a quarter of no fever is met with in this disease. Possibly the previous history of slow continued and remittent fever may have had some influence on the temperature.

---

[1] Abstract of a paper read before the St. Mary's Hospital Medical Society on Dec. 11th, 1901.

The patient, an adult male, was admitted to hospital on Nov. 18th, 1901, and came under my care on Dec. 6th. With the exception of his temperature chart there was no record of his symptoms during that time. The temperatures recorded on the first three days in hospital were as follows:—Nov. 18th: evening, 104·6° F. Nov. 19th: morning, 104·6°; evening, 104·8°. Nov. 20th: morning, 103·8°; evening, 104·4°. From this date there was a steady decline till Dec. 5th when the temperature in the morning was 100·8° and in the evening it was 98°. In May, 1899, he had contracted primary syphilis at Aldershot, and during April, 1900, was under treatment for secondary syphilis at Malta. During his service in Malta he was subsequently treated for remittent fever and slow continued fever. When he came under my care he presented the following appearance. The face was thin, pale, and slightly cyanosed; there was constant cough with very little expectoration, the sputum in 24 hours only amounting to about one ounce, chiefly mucus, and on a few occasions a slight reddish tinge was noticed. Both lungs were dull on percussion, particularly at the bases, with great resistance to the finger; vocal resonance was increased; tubular breathing was heard over the bases and there were a few râles and a large number of rhonchi. Over the apices and front of the chest the breath sounds were more bronchial and the rhonchi were less. The respirations ranged between 20 and 26 per minute. The pulse-rate was 100. The heart sounds were regular but weak. The bowels were moved regularly twice a day. There was delirium at times. The temperature in the morning was 99·4° and in the evening it was 97·8°. On Dec. 7th it was 101·2° in the morning and 101·0° in the evening. From Dec. 10th to the 28th inclusive the temperature did not rise above 98·8°, except on the evenings of the 11th, 13th, 16th, and 17th.

On Dec. 13th the patient was put on 15-grain doses of potassium iodide three times a day and daily inunctions of mercury. On the 24th the temperature had practically been at normal for some days; the cough was almost gone; percussion over both lungs was normal and there were no rhonchi or râles. The man was quite sensible; he slept well and was able to sit up. On the 27th the cough had become more troublesome again, and I at the time attributed this to his bed being rather near a draughty window. He still seemed to be in good spirits and was quite sensible. On the 29th the temperature rose to 103·2°. The face became somewhat cyanosed and the old symptoms in the lungs returned. In spite of the dose of potassium iodide being increased to 30 grains he gradually passed into a typhoid state and died on Jan. 7th, 1902. The respirations reached 55 per minute three days before death, but they dropped on the 6th to 22.

It is a matter of great regret that no post-mortem examination was allowed. The diagnosis was founded on the distinct history of syphilis and the remarkable clearing up of all symptoms under anti-syphilitic treatment. The secondary and fatal attack showed the only temporary subsidence of the disease under treatment.

# A NOTE ON A FAMILY EPIDEMIC OF IMPETIGO CONTAGIOSA BULLOSA ORIGINATED BY PEDICULI CAPITIS.[1]

BY GEORGE PERNET, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE PATHOLOGIST, BLACKFRIARS HOSPITAL FOR DISEASES OF THE SKIN.

WHILST in charge of the Skin Department of University College Hospital last September four children of the same family were brought to the out-patient room. I will shortly describe the cases in the order in which they were observed.

CASE 1.—The patient was a boy, aged two years and 10 months, with an eruption of two days' duration. It had commenced as a water-blister on the left forearm and had then spread to other parts of the body, trunk, &c. The mother, an intelligent woman, stated that the lesions commenced as vesicles of the size of hemp seeds which rapidly enlarged, attaining the diameter of a pea and later of a halfpenny, when they burst. As a result of this there were found on examination about a dozen recent superficially excoriated areas, about one inch in diameter, and looking very like what is observed in involuting pemphigus neonatorum. On the outer side of the left leg there was a vesicle of the size of a lentil, with clear contents and an erythematous areola. The mother said that the child had been feverish; on taking the temperature, however, it was found to be only 99·6° F.

CASE 2.—The patient was a boy, aged eight years. He had only been affected since the previous night, when a water-blister of the size of a pea was noticed on the back of the head. It was stated to have burst and the lesion to have since extended. When I saw him there was a crusted, superficially excoriated area a quarter of an inch in diameter, with surrounding redness.

CASE 3.—The patient was a girl, aged 13 years. In her case the eruption had been present for 10 days. It began on the right thumb as a scratch, came up as a blister, and burst. Three days later the face became involved. I found a reddened circular area of the size of a sixpenny-piece over the metacarpo-phalangeal joint of the right thumb. On the face there were several slightly crusted, reddened areas of the size of hemp seeds, some of which had coalesced, forming little patches each of the size of a finger-nail. These, the mother stated, had been originally vesicular. The child had been away in the country for a holiday with the patient in the following case.

CASE 4.—The patient was a girl, aged 10 years. Her eruption had been present for 10 days. It began as a white blister containing water on the lobe of the right ear. There were a reddened circular dry area one inch in diameter on the dorsum of the left hand, a similar one about a quarter of an inch in diameter on the right wrist, and a few drying-up pustules about the occiput and the right ear. The pustular lesions of the occiput led me to examine for pediculi. I found numerous nits. This gave the key to the whole thing. There were no pediculi in the other children.

In connexion with the above I may mention that I have seen pemphigus neonatorum occur where the three other children of the family all had marked impetigo contagiosa of the ordinary type. I had no doubt in that case that the infant had contracted the bullous eruption from the other children.[2] I was asked to see the child because it was thought to be a case of congenital syphilis. I found that the family lived in one upstairs room and the mother assured me that the house was quite healthy. I have also seen pemphigus neonatorum in sucklings whose mothers were suffering from abscess of the breast.

In the cases of bullous impetigo contagiosa which I have described above the youngest child had best presented the bullous type, no doubt on account of the greater delicacy of the skin. In him the lesions looked like what is seen in subsiding pemphigus neonatorum and the lesions had not the crusted appearances usually associated with ordinary impetigo contagiosa, whereas some of those in the older children had.

I am indebted to Dr. H. Radcliffe Crocker for kindly allowing me to make use of the cases.

Upper Gloucester-place, N.W.

SMALL-POX AND ISOLATION HOSPITALS.—The following municipal authorities are either discussing sites or have decided to erect small hospitals:—Pinner Parish Council (small-pox), Staines Rural District Council (temporary small-pox), Warmley (isolation), Tredegar (cottage), Easingwold (isolation), Launceston Town Council (isolation), Haywards Heath (small-pox), Canterbury (extension of nurses' quarters at the sanatorium), Oswestry District Council and Town Council (joint isolation), Barrow County Council (small-pox), Kingswood Rural District Council (isolation), Beaconsfield Urban District Council (isolation), Bideford (new infirmary at workhouse, £4000), Berwick Sanitary Authority (infectious diseases hospital), Lutterworth (isolation), Dunstable Town Council (isolation), Wellingborough (temporary small-pox), Luton Rural District Council, and Eaton Bray District Council (isolation), Slough Guardians (isolation), Towcester (small-pox), Thetford (isolation, borough proposed joint scheme abandoned), and Chard Rural District Council and Town Council, Crewkerne Urban District Council, and Ilminster Urban District Council (joint isolation).

fault of the latter, not of the auscultator. Again, in the differentiation of mitral murmurs the double stethoscope leaves much to be desired. I have constantly found that systolic murmurs have been described as presystolic when this instrument has been employed, though the converse mistake has not occurred. And in the study of the normal heart sounds I have found the diagnosis of "over accentuation" or "obscurity," neither of which really existed, to be constantly made. As regards the heart, therefore, I look upon the use of the binaural stethoscope as being in every way most objectionable. As regards the diagnosis of heart disease there is no middle course. The double stethoscope should be altogether done away with and abolished off the face of the earth—*Delenda est Carthago.*

Next as concerns the examination of the lungs. Here, again, there is nothing good to be said as regards the use of the binaural instrument in its strictly auscultatory aspect. On the contrary, it is easy to point out numerous and grievous faults. I have noticed that beginners who are learning the elements of diagnosis of chest disease, and who, alas, are freely allowed to choose their instrument, never really appreciate the difference between bronchial, tubular, and cavernous breathing. I do not for a moment deny that this inability may to a certain extent depend upon the want of a keen and correct hearing sense; probably this is so to some extent. But making every allowance on this account, I maintain that this great fault is due chiefly to the most foolish and injudicious laxity which permits to a young and inexperienced student the use of an untrustworthy and deceitful instrument. This failure to recognise fine shades and distinctions of sound is practically always attributed to the defective "ear" of the observer. In nine cases out of ten it is nothing of the kind; on the contrary, it is the result of a defective system of education. the differentiation of friction sounds and of crepitation is by no means easy at any time; when the binaural stethoscope is made use of such discrimination is absolutely impossible. And the tendency of the instrument is invariably to exaggerate the pulmonary sounds, whether healthy or morbid, to a degree which is embarrassing and likely to tend to serious error in diagnosis. Further, the fact of both ears being occupied with the examination renders it impossible to appreciate the significance of what is heard by comparison with the unoccupied ear; this is a very important point and one not adequately recognised.

So much, then, for the disadvantages of the double stethoscope from the point of view of diagnosis. But there is another side to the question. Common sense tells us that it cannot be good for the delicate organ of hearing to be more or less constantly compressed by the ivory heads and the unyielding spring of the binaural stethoscope. For it must not be forgotten that when the instrument is made use of the pressure of the necessary spring is by no means a negligible quantity. Without a certain, indeed, a considerable, tension nothing can be made of the sounds heard within the chest, and I am strongly of opinion that the minimum pressure required for this purpose does not remain confined to the parts on which the ivory heads immediately impinge—i e., to the outer portion of the external meatus—but that it is transmitted to the rest of the canal and to the membrana tympani. It cannot be denied, therefore, that this pressure kept up intermittently for hours, as is the case with house physicians and others, may be most injurious to the hearing of the observer. I have known of extreme tenderness being the result of the use of the instrument; so marked, indeed, was this symptom that in more than one case experience has taught the sufferer at once to discontinue the use of the instrument, in order that worse evil might be avoided. The delicate organ of hearing is not intended to be abused in this manner, and pain and discomfort in the ear are the first warnings that nature is being trifled with; such warnings are not to be neglected with impunity.

Are there, then, no uses for the binaural stethoscope, or is the instrument to be altogether condemned? It may be said at once that the use of the double stethoscope should be altogether discarded were it not for the fact that it is convenient in illnesses which render it difficult to move the patient in a manner suitable for examination by the wooden stethoscope. In many cases of enteric and other fevers, in pneumonia, and other conditions in which it is undesirable on account of the feebleness of the patient to move him more than is absolutely necessary the binaural stethoscope is often of use in enabling the breath sounds to be heard, when this would be possible only with the greatest difficulty were the wooden instrument made use of. In babies, again, and in young children, the double instrument may be advantageously employed. But used in this way the stethoscope in question is merely an accessory, one to be employed for particular occasions and for special needs. What I protest against, and in the strongest possible manner, is the predilection shown for the binaural stethoscope by the young student who is allowed to make use of it from the very commencement of his clinical work, so that he is totally unable to appreciate the advantages which appertain to the employment of the old-fashioned instrument. No words can condemn too strongly this adoption of the binaural instrument which is, I am convinced, the cause of much of the indifferent diagnosis of chest disease so often observed at the present time.

Wimpole-street, W.

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### FOREIGN BODY A LONG TIME EMBEDDED IN THE HAND.

By L. K. Herschel, M.D. Vienna.

The following short account of a case in which a fragment of glass remained embedded in the muscles of the hand for nearly three years may be of interest as showing the usefulness of non-interference when no danger can arise from waiting.

In March, 1899, the patient, who was engaged in the analysis of fats in the chemical laboratory of the University of Jena, unfortunately broke a glass jar while forcing a stopper into it. The palm of one of his hands was wounded in a line with the middle finger at a point nearly opposite to the middle of the metacarpal bone of the thumb. A jet of blood immediately spurted out as high as the ceiling and an artery was ligatured by a surgeon. A branch of the radial nerve was also severed, for numbness at once appeared on the inside of the thumb and on the outside of the forefinger. (This still continues to a slight extent.) At the time of the accident the surgeon who tied the artery discovered no foreign body, but an x-ray photograph taken five days afterwards showed a shadow of an abnormal character. There were, however, no urgent symptoms; the wound healed without suppuration, and in order that the ends of the artery might have time to consolidate the surgeon advised non-interference. After three weeks, the appearance of the hand being quite normal, the surgeon endeavoured to remove the foreign body which from the x-ray photograph was supposed to be just under the surface, but the attempt was unsuccessful. All remained quiet until a few months ago. The patient, who was a violinist, had given over playing on account of the injury, but on resuming it he occasionally had painful sensations in the back of his hand in the triangle between the metacarpal bones of the thumb and forefinger. In the first week of January, 1902, he felt considerable pain in this triangle when washing and drying his hand, and a red spot formed on the back of the hand almost on a level with the carpo-metacarpal articulation. On Jan. 10th the skin gave way at this spot and a sharp point protruded; two days afterwards, as it was coming more and more to the surface, the patient seized it with a pair of forceps and drew out a fragment of glass five-eighths of an inch long. No pain or difficulty was experienced in doing this and the wound closed without suppuration.

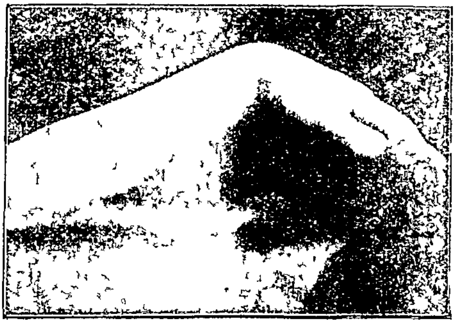
Bordighera.

### A CASE OF SYPHILITIC PNEUMONIA.

By John George Gibbon, M.D. Dub.

That the following case was one of syphilitic pneumonia there can, I think, be little doubt. The course of the temperature was interesting as most of the few authorities to whose works I have been able to refer mention that little or be called normal shortening which occurs when the tendons of healthy muscles are divided The remaining tendons were then divided similarly, their corresponding ends being loosely tied together for identification until their suture was completed, fine silk being used for this purpose The wound was closed without drainage and the fingers were put up in slight flexion For some weeks after movement was commenced, and even after it became free and unrestricted in range, the muscular power remained very feeble but eventually it began steadily to improve and when the patient was last heard of she had resumed work with perfect movement of the fingers and a fair grip

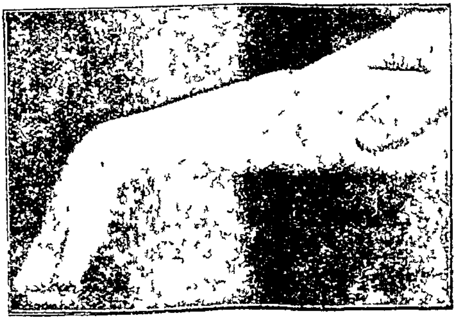
FIG 1



Showing flexion of wrist on extension of fingers

CASE 2.—A boy, aged 12 years, was admitted into the Leeds General Infirmary on Jan 30th 1901, with a crippled and useless hand the result of an injury received three years before He fell off a ladder and "broke the right arm between the wrist and the elbow" Splints were applied in front and behind and were kept on for about *10 weeks* (?) At the end of that time when the splints were removed on account of offensive discharge from beneath them, there was a large deep sore in front of the elbow and the fingers were bent and stiff and useless The wrist and elbow joints were also bent and stiff The boy stated also that "the skin came off the back of the fingers and the nails came away and there was very little feeling in the fingers—none at all in the forefinger", but he was not very clear about dates and sequences The fingers slowly healed and became less numb and by degrees he could move the elbow again but the stiffness of the wrist and fingers got no better—perhaps it grew a little worse—and for the last two years the hand had not altered except that from time to time the backs of the fingers became sore On admission neither the wrist nor the fingers could be straightened to any appreciable extent, but the metacarpo phalangeal joints were distinctly hyper extended (The attitude is well shown in Fig 2.) The thumb was stiff and contracted at the inter phalangeal joint. The fingers were smooth, shiny, and livid, and on the dorsum of the second phalanx the index third and fourth showed irritable looking tight scars of former ulceration Sensation was much impaired over the median nerve distribution in the fingers and to a less extent in the ulnar The radial nerve was unaffected. There was a large and somewhat contracted scar in the middle of the forearm just below the bend of the elbow It was about one and a half inches wide by two inches long (Unfortunately, the electrician's reports in the two cases are not forthcoming Being written on much smaller paper they have been lost )

FIG 2



Showing hyper-extension of metacarpo-phalangeal joints

A similar operation to that in Case 1 was performed on Feb 8th, except that the tendons were exposed by a longitudinal incision extending five inches upward from the annular ligament, on the radial side of the palmaris longus tendon, which was much contracted and was cut away, and the flexor longus pollicis also required lengthening On the sixth day the dressing was changed on account of a rise of temperature to 99 8° F, unaccompanied by pain or any other disturbance, and a small superficial suppuration was discovered. The temperature immediately fell again to normal and thenceforward the progress of the wound was uneventful In this case the split tendons were cut flush and sutured end to end, and the hand was secured with the wrist in slight flexion Owing to the occurrence of the suppuration passive movement was postponed and shortly after it was commenced the boy's father removed him from the hospital in consequence of his outcry about the discomfort of the passive movement He has been lost sight of

*Remarks by* Mr WARD —The practical importance and the considerable interest both clinical and pathological, of the condition, to which further attention has been drawn by a valuable paper contributed to THE LANCET of Jan 11th, 1902, p 78, by Mr L S Dudgeon, encourages me to hope that reports of additional cases may not be without value I therefore record brief histories of the two cases of this affection most recently under my care, and I propose to supplement them by a few remarks upon some of the views which have been propounded as to its causes and its nature, and upon the indications for, and the results of active surgical treatment My personal experience of the affection goes back well over 20 years, long before, I must confess, I knew of Volkmann's original description. Impressions are fallacious, I know, but if I were to say that I had seen an average of one case a year since 1877 I do not think I should be overstating

The two cases published by my colleague, Mr H Littlewood,[1] about two years ago, and the two which I report, were operated upon in the Leeds General Infirmary between Dec 5th 1898 and Feb 8th, 1901, a little over two years, and I do not think that this much over represents the frequency with which these cases have come up during the last 25 years to consultations of the surgical staff, the odium, generally unmerited of the casualty room and the despair of the surgeons

For a considerable number of years I believed that the condition was the result of one uniform cause—that is, fracture at or near the lower epiphysial line of the humerus treated by the application of an anterior rectangular splint, and it is not until comparatively lately that I have known or heard of any exception, indeed, the history might almost be stereotyped as follows "A child from five to eight years of age sustains a severe injury to the elbow which causes swelling, a deformity which includes some increased prominence of the olecranon and shortening of the forearm, abnormal mobility in certain directions, and crepitus. An anterior (and perhaps a posterior) rectangular splint is applied and the child is allowed to go home. No excessive amount of pain is complained of, or if so it is disregarded, and the child is not brought up again till the blue and swollen condition of the fingers shows that something is seriously wrong Then the splint is removed, disclosing an area indicating severe pressure either a slough or a sore, over the fleshy bellies of the flexor muscles Also splint cannot be re applied and the arm is placed in a sling With the subsidence of the swelling the bony deformity

## LONDON TEMPERANCE HOSPITAL.

### A CASE OF PERFORATED GASTRIC ULCER; LAPAROTOMY; SUCCESSFUL CLOSURE BY SUTURE; DEATH EIGHT DAYS AFTER FROM HÆMORRHAGE FROM DUODENAL ULCER.

(Under the care of Dr. W. J. COLLINS.)

IN one-fifth of the recorded cases of perforating gastric ulcer two perforations are present, but it is very rare for a duodenal ulcer to perforate at the same time as an ulcer of the stomach.[1] Still more rare is it for a duodenal ulcer to perforate some days after the suturing of a gastric ulcer, though it is not so rare for a second gastric ulcer to perforate a few days after the first perforation. Inasmuch as the etiology of duodenal ulcer seems to be similar to that of ulcer of the stomach we need feel no surprise at this occasional coincidence. In the following case the onset of the duodenal perforation does not seem to have been sufficiently acute to render a second laparotomy advisable.

A fairly nourished but rather anæmic young woman, aged 23 years, who had had attacks of dyspepsia but gave no history of hæmatemesis, was admitted to the London Temperance Hospital on the evening of April 8th, 1901, about 12 hours after a sudden and violent attack of pain in the abdomen accompanied by marked collapse. On admission the abdomen was tense and tender in the epigastric region; breathing was thoracic. The temperature was 101° F. and the pulse was 128 and running. Dr. W. J. Collins saw her at once and decided to open the abdomen, diagnosing the presence of a perforated gastric ulcer. Under chloroform the abdomen was opened in the mid line above the umbilicus; gas escaped on incising the peritoneum. The index finger detected a roughened surface and edge high up on the anterior surface close to the cardia. By retracting firmly the left lobe of the liver and the costal cartilages the ulcer was brought into view surrounded by shaggy yellow lymph. The contents of the stomach were escaping into the peritoneum. Three Lembert's sutures were with a little difficulty inserted and then two circular sutures were put in and the ulcer was securely closed. The peritoneum was cleansed as effectually as the desperate condition of the patient permitted and a gauze-drain was inserted down to the sutured ulcer.

On April 9th the patient was fairly well; there was no pain and the abdomen was not distended or tender. The temperature was 101°. She was fed by the rectum. On the 10th she slept for five and a half hours. She was thirsty. A quarter of a grain of morphia was injected hypodermically. The breathing was rapid. On the 12th some turbid serum from the wound was found on the dressing The patient had an attack of parotitis (right). The bowels were opened. On the 13th she said that she felt well; the parotitis was less; the discharge from the wound was rather offensive; the wound was swabbed out with carbolic lotion. On the 14th a dark motion was passed (melæna). The discharge from the wound was purulent. On the 15th anæmia was more marked. The patient was restless and breathless. A tar-coloured motion was passed. On the 16th the stool contained blood-clots. The pulse was very rapid. A copious hæmorrhagic motion was passed and death took place at 3 15 P.M.

*Necropsy.*—The whole of the intestines contained blood. Half an inch from the pylorus there was a duodenal ulcer of the size of a five-shilling piece with undermined edges and covered with blood-clot; the walls of the gut were very thin. The stomach was coated with shaggy lymph round the cardia and there was a small subphrenic collection of pus. The sutures were not seen; the site of the perforated ulcer was watertight and on the inner surface was seen a dimple-like depression measuring one and a quarter inches by a quarter of an inch.

## LEEDS GENERAL INFIRMARY.

### TWO CASES OF VOLKMANN'S CONTRACTURE.

(Under the care of Mr. WARD.)

WHEN the exact etiology and pathology of a morbid condition have not been fully ascertained it is far better in naming it to choose a title which is as little connotative as possible. Therefore the name "Volkmann's contracture" (although there is no doubt that as a rule it is objectionable that a disease should be described by an individual surgeon's or physician's name) is far more suitable for the condition which was first described by that surgeon than "ischæmic paralysis," which attempts unsuccessfully to describe its cause and its nature. The two cases of this condition described below are a useful addition to Mr. L. S. Dudgeon's paper in THE LANCET of Jan. 11th, p. 78. It will probably be found that the condition is fairly common, but its apparent unsuitability for surgical treatment has hitherto prevented most of these patients from entering the hospital wards. It is highly desirable that many cases should be recorded in order that we may be enabled to form a comparison between the two chief methods of treatment—namely, tendon-lengthening and massage accompanied by electrical treatment.

CASE 1.—A young woman, aged 21 years, a weaver, was admitted as an in-patient of the Leeds General Infirmary under the care of Mr. Ward on Jan. 24th, 1900, complaining of stiffness and weakness of the left forearm and hand, with inability to straighten the fingers and wrist, so that she was incapacitated from pursuing her occupation. Six weeks previously she sustained an injury to the forearm in the following manner. She was a power-loom weaver and while at her work she thoughtlessly put her hand into the loom to adjust something in motion. The advancing beam caught her arm and crushed it momentarily against the front frame of the machine, in a space said to be reduced to little more than an inch in width. The arm was instantly released as the beam receded. The arm swelled very much almost immediately. The skin was not broken. She was seen by a medical man who found that there was no fracture and the limb was simply placed in a sling and she supposed that her fingers rested comfortably bent. The swelling subsided slowly and it was not until about three weeks afterwards that attempts were made to straighten the fingers, when it was found to be impossible. These attempts had been steadily persevered in up to the time of her admission, but in spite of them she had grown a little worse. So far as she could tell, sensation had never been interfered with, but she took no special notice of this point just at first, during the worst of the pain and general disturbance. As the swelling subsided a depression was observed on the front of the forearm, about the middle, more marked towards the ulnar side. Briefly, the condition was as follows. The wrist and fingers could not both be straightened at the same time. If she extended the wrist the fingers flexed at the inter-phalangeal joints, the metacarpo-phalangeal remaining extended. If she extended the fingers the wrist flexed to an angle of about 60° with the axis of the limb (Fig. 1), and somewhat more if the middle finger was forcibly extended till it was quite straight. The thumb was not affected. Sensation in the affected fingers was normal. Immediately below the middle of the forearm was a well-marked scar-like depression of the skin, although there was no actual scar. Beneath this depression was a leathery induration apparently in the substance of the muscles. Movement of the fingers showed the depressed patch of skin to be somewhat adherent to the deeper parts. A skiagram revealed distinct thickening and blurring of the interosseous border of the radius, but nothing to indicate any fracture.

Operation was performed on Feb. 12th. The tendons were exposed by turning up a rounded flap just above the annular ligament. The tendons of the ring finger were split for a length of two inches and divided in opposite directions at opposite ends of the split. The finger was then straightened and it was found that the overlapping was reduced from two inches to a quarter of an inch, which was much more than was expected, though, of course, some of this was what may until all the tendons have been divided. Here the additional amount to be allowed for extension of the wrist must be estimated by the judgment of the surgeon. 3. With the fingers and wrist straightened, should the tendons be secured in some degree of tension or with the muscles in complete relaxation? It might be argued that the reproduction of something like the normal muscular tone and tension is more likely to preserve the greatest possible amount of muscular power—that to leave the muscles flaccid involves a certain further degree of contracture before effective voluntary contraction can come into play. On the whole, however, I am inclined to think that it is better not to suture under tension. 4. I was tempted in the second case, after determining the exact amount of lengthening required, to cut the ends flush at slightly different levels for the different tendons, and to suture end to end with the object of securing a much neater junction with less risk of subsequent adhesions and tethering. In this case some suppuration occurred and it caused me much more uneasiness as to the union than if the ends had been left overlapping. 5. I believe that the best position, until passive movement is commenced, is one of slight flexion of the fingers. If the fingers and the wrist are in complete extension it is obvious that no further movement is possible in the only direction which is effective for breaking down adhesions. And if the lengthening has been sufficient, and the operation not performed too early, this slight flexion is not likely to predispose to further contracture.

## PATHOLOGICAL SOCIETY OF LONDON.

*Exhibition of Specimens.*

A LABORATORY meeting of this society was held on Feb. 4th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Dr. NORMAN DALTON showed sections of a Syphilitic Patch on the Pharynx showing Hyaline Fragmented Bodies. The patient was undoubtedly syphilitic and died from phlegmonous inflammation of the fauces. One or two white patches were found on the pharynx. These proved to be patches of acute inflammation with infiltration of leucocytes as deep as the muscular layer, and around the vessels a fibrinous exudation. In the connective tissue round the mucous glands numerous hyaline bodies were seen. Many of these when examined with the higher powers of the microscope were found to be broken up into small rounded or slightly angular fragments. They stained deeply with eosin and the orange of Ehrlich-Biondi's stain. The hyaline bodies were also found between the columnar epithelial cells which lined the gland acini. Their position both outside and inside the glands suggested that they were once amœboid cells. There was some doubt as to whether the nuclei which appeared under the low power to be in the bodies really belonged to them. Dr. Dalton thought that they did, but that the nuclei were pushed to the extreme periphery of the cell by the swelling of the cell protoplasm which had undergone the hyaline change. He thought that the bodies were connective-tissue corpuscles which had undergone a hyaline degeneration like Zenker's degeneration of muscle, because (1) they appeared to have been once amœboid; (2) their nuclei (allowing that the nuclei really belonged to them) were like those of young connective-tissue corpuscles; and (3) their close resemblance to certain hyaline bodies which Unna had described in connexion with actinomycosis and which he considered to be degenerated plasma cells (the latter being derived from connective-tissue cells). Dr Dalton also showed the same hyaline bodies in an ulcerated vaginal wall from a case of syphilis. He thought that the degeneration was produced by the syphilitic toxins in these two cases.

Dr. ARTHUR WHITFIELD showed a short series of Specimens stained with the Methyl Green Pyronin Stain of Pappenheim. The series comprised sections of Paget's disease, actinomycosis, syphilis, and a piece of granulation tissue from the interior of an inflamed knee-joint. The object of the stain was to differentiate the cells named by Unna "plasma cells," which were probably not in all cases identical with those described by Waldeyer under the same name. The method of staining was published in the *Monatshefte fur praktische Dermatologie*, vol. xxxiii., No. 2, and in Virchow's *Archives*, vol. clxvi., No. 3. Shortly stated, the method depended on the fact that methyl green, although a basic stain, was limited in its action to the staining of chromatin, while pyronin, also a basic stain, showed a strong affinity for basophile protoplasm. It was thus found that on staining sections by this method one obtained a clear bluish-green colouration of the nuclei of the plasma cells while the protoplasm became bright red. The reaction was identical in the case of the hæmic lymphocytes, but the rim of protoplasm was much smaller. The stain was therefore not capable of distinguishing these cells from one another, but was extremely useful in the study of the cells in inflammatory infiltration to enable the plasma cells to be picked out rapidly, and the nucleus of the plasma cell was distinguished clearly from that of the ordinary lymphocyte. As regarded the factors influencing the certainty of the stain he had found that the stain worked best in specimens that had been hardened in alcohol, that it was also fairly satisfactory in sublimate specimens, but that formalin specimens, although allowing the stain to be used, showed a certain mingling of the colours, the protoplasm becoming slightly purple and the nucleus violet.

Dr. R. T. HEWLETT described some Experiments which he had performed to test whether Diphtheria and Tetanus Antitoxins were absorbed from the Stomach or Rectum. Guinea-pigs were fed with varying amounts of antitoxin and were then injected with a single acute lethal dose of diphtheria or tetanus toxin. In no instance was the slightest protection manifested. Similarly, rabbits received rectal injections of diphtheria or tetanus antitoxin on several successive days, and were then inoculated with minimal doses of toxin, again with the result that not the slightest protection had been conferred by the rectal injections. Dr. Hewlett pointed out that although these results were not new it did not seem to be known generally that antitoxin was not absorbed by the mucous membrane of the stomach or rectum, and reports were frequently being published in the medical journals of cases treated with antitoxin by the mouth.

Dr. C. W. DANIELS showed a specimen of Avian Filaria from British Guiana, sent to him by Dr. C. R. Kennard. The series of embryos were from five species of birds and two of these had filaria of two species, so that in all there were embryos of seven species of filaria. The adult forms, male and female, of three species only were found. The embryos in most species differed markedly from each other. They varied in size, the smallest being only 65μ in length whilst the largest was 256μ. Only one species had a sheath. They differed also in relative proportions, in shape, and particularly in the character of the tails. As regards structure, some stained more readily than others and the nuclei forming the central mass of the embryo was packed more closely in some species than in others. In most filarial embryos there was a gap in the central nuclear mass and sometimes two gaps. The position of this gap and its size were fairly constant in the different individuals of each species. In that of the ostinops it was of unusual size, being about 10μ in length. As regards the adults, the male of the filaria of the crotophaga ani was remarkable in that it was much longer than the female, whilst as a rule to which exceptions were rare the female was the larger. There were two unequal spicules in the male. In the crotophaga ani the adults of two species differed considerably though the embryos differed but slightly. In both there were two unequal spicules, the longer being situated anteriorly. In the smaller of these males the tubular nature of the longer spicule was well shown as well as its connexion with the tubular expansion in the interior into which the vas deferens opened, as the whole of this combined tube was occupied by an air bubble. The adults were found, in the case of the ostinops, in a cyst connected with the craw. In the crotophaga (old witch) they were beneath the loosely attached mucous membrane of the craw. Whether these avian filaria caused any symptoms was unknown. The life-history and intermediate hosts had not been traced. The situation of the adult worms in connexion with the alimentary canal was of interest and suggested that the worms were introduced through the mouth, and in this connexion it was worthy of note that in two at least of the human filariæ the adults were found near the stomach and in these two all attempts at infection of many species of mosquito and of some other insects had failed.

about the elbow becomes more distinct, especially an anterior prominence towards the inner side just above the joint; and presently it is noticed that the fingers are bent and stiff and that they cannot be straightened without coincident bending at the wrist. The fingers are smooth and glossy, with varying degrees of anæsthesia, and (in most cases) ulcers appear on the dorsum of the second and third phalanges." I believe that this history still fits the majority of the cases, but now we know that well-marked exceptions must be admitted.

Speaking from recollection, the earlier cases were all of the severer type, with considerable anæsthesia; frequently with scars or ulcers over the dorsum of the second and third phalanges; usually a scar on the front of the forearm, and such a degree of contracture that any attempt to straighten the fingers simply increased the flexion of the wrist without much effect upon the fingers themselves.

This common occurrence of anæsthesia and trophic ulcerations among the earlier cases led us at first to the opinion that the whole condition was due to splint pressure upon the ulnar and median nerves, but the later appearance of cases possessing unimpaired sensation and preserving the integrity of the intrinsic muscles of the hand led to the surrender of this opinion and to the adoption of the view that local damage of the muscles from severe and prolonged pressure just short of the production of actual gangrene of them, but resulting in destruction of the muscle elements and their later substitution by contracting fibrous tissue, must be regarded as the real and primary cause of the shortening. It is much to be regretted that these earlier cases were not carefully and permanently recorded, but unfortunately, owing to the chronic circumstance of pressure on our beds, they were not taken into the wards; for the failure of a few attempts at forcible extension under anæsthesia, together with the apparently hopeless stationary condition of one or two cases which were kept under occasional observation for a year or two, had developed a discouraging conviction that nothing more could be done for them as in-patients

It will be seen from the history of the accident and its treatment in Case 1 that ischæmia cannot be accepted as the only, the invariable, precursor of the shortening of the muscles. The contusing force was a sudden and momentary one; neither splint nor bandage was applied from beginning to end; and as the injury was at a distinctly lower level than usual it is hardly likely that the muscles could be starved in their main bulk from a protracted interference with their blood-supply. The case reported by Mr. H. L. Barnard[2] emphasises, but not quite so forcibly, this point. On the other hand, Mr. Littlewood's argument from his case where the splint sore was on the back of the forearm is not very strong, for here the pressure is taken by the ulna, not the muscles, and it might fairly be contended that ischæmia of the flexor muscles was caused by the bandages with which the splint was secured, assuming that there was not an anterior splint as well.

The remarks which I have to offer on the two cases recorded above will not, I fear, contribute anything very material to our knowledge of the injury, but for some time yet it may be worth while to report cases as they occur, and especially, perhaps, any which have been subjected to active treatment or which have been known to recover without it.

It is desirable that some confusion and diversity of opinion should, if possible, be cleared up and reconciled. Compare, for example, the two following very positive statements. "It is a result of prolonged fixation of forearm fractures by any form of apparatus which intercepts the free circulation of the blood through the muscles and nerves of the part" (Anderson). "I do not believe that splint pressure has anything to do with the deformity. It will be found that the injuries have been severe and that the flexor muscles have been torn. The torn muscle is replaced by fibrous tissue, and this, contracting, is, I believe, responsible for the deformity" (Littlewood). The first of these statements, except for the error as to the usual seat of the fractures, still remains, in my opinion, the correct explanation of a large majority of the cases, although it must be understood, of course, that it is the pressure on the muscles which is the direct cause of the changes leading to contracture, and not the pressure upon the nerves, which gives rise to those frequently associated manifestations which are not an essential part of the affection.

Case 1, here reported, seems to prove, however, that it is not the explanation of all cases. The simple fact is that the removal or destruction of a length of flexor muscle and the substitution for it of scar tissue may be brought about in a variety of ways.

I still think, in spite of Mr. Littlewood's opinion to the contrary, that in most of the cases where it ensues upon fractures about the elbow it is the unfortunate result of the treatment and not of the original injury. I do not admit that these injuries about the elbow, whether dislocations backward or fractures in the lower end of the humerus, cause such extensive lacerations in the bellies of the flexor muscles as will give rise to serious contracture and structural shortening. If that were so, I fear that Volkmann's contracture would unhappily be far more common than it is, for I have a very decided recollection that some of the earlier cases which I have seen were regarded in the first instance as injuries of no great gravity and not serious of their kind. The lump which the indurated patch sometimes makes in the muscles is found immediately beneath the pressure scar or sore when such exists (Mr. Littlewood's case of dorsal scar notwithstanding).

If the supporters of the "ischæmic" theory and their opponents would each admit that the others are right the ground would be cleared for an understanding. Personally, I am not sorry that the words "ischæmic" and "palsy" are dropping out of the definition. "Volkmann's contracture," although open to the general objection to the use of proper names, is a concise and sufficient label and it involves no theories. The more detailed and descriptive definition given by Mr. Dudgeon is very satisfactory.

A word or two about the "swelling, bony in character, sometimes found at the lower end of the humerus, generally at the inner side," which is occasionally referred to as if it were part of the affection. Of course it is not. It is only present in those cases which are associated with fracture or epiphysial separation at the lower end of the humerus, and is, in fact, the lower end of its diaphysis, from which the lower fragment or the epiphysis has been displaced backwards. It is to be found in most cases of faulty union at this point, whether associated or not with Volkmann's contracture, with which it has no essential connexion. When it is of such degree as to cause mechanical locking and seriously to limit the flexion of the elbow it may readily be removed by the chisel—an operation which I have several times practised with satisfactory results.

The prognosis in Volkmann's contracture is an important matter, for it has a significant bearing upon the question of treatment. Here in Leeds, in spite of the very confident statements made by some authorities that many of the cases eventually recover, we have been accustomed to regard them as hopeless, and certainly some of them have remained under observation for considerable periods without a sign of improvement. If the pathology of the condition is to be regarded as identical with that of the type of torticollis with which comparison has been made this unfavourable view must be admitted to be the correct one. But one somewhat pertinent fact may be noticed. I have never seen or heard of any adult with Volkmann's contracture due to, and persisting from, injury in childhood; and, moreover, although some of our cases were kept under observation for considerable periods, none of them were kept long enough to be accepted as conclusive upon the point.

If it can with any confidence be anticipated that cases will recover under the treatment advocated and carried out by Mr. Dudgeon few surgeons will, I imagine, submit patients to an operation of appreciable uncertainty and in which failure would probably leave greater crippling than before. It is difficult to understand, however, by what natural processes the damaged muscles themselves can undergo repair—at any rate, in those cases in which there is considerable destruction and actual loss of substance, and such cases make a large percentage of the whole.

With regard to the technique of the tendon-lengthening operation there are a few points of detail which deserve comment. 1. I quite agree with Mr. Dudgeon that cases should not be subjected to operation until it is reasonably certain that the contracture has reached its limit. 2. To determine how much lengthening may be necessary in a given case, so as not to denude and to split all the tendons more than can be avoided, it is an advantage to select the tendons of one finger, say the ring finger, to make a two-inch split, to straighten the finger, to observe how much of the overlap has been taken up, and to divide the other tendons accordingly. In the worst cases the wrist cannot be straightened influence of these rays on lupus he attributed to their burning action. No good effect resulted unless the treatment was accompanied by at least some symptoms of burning. He did not think that the Roentgen rays afforded any marked superiority over the best of the old-fashioned methods of treating lupus. The x rays were in the majority of cases inferior to the arc lamp rays in the treatment of lupus.—The PRESIDENT, Dr. ALEXANDER, and Mr. G. P. NEWBOLT spoke, and Dr. TAYLOR replied.

# *ROYAL ACADEMY OF MEDICINE IN IRELAND.*

## SURGICAL SECTION.

### *Synovitis.—Pylorectomy.—Exhibition of Cases.*

A MEETING of this section was held on Jan. 17th, Mr. THOMAS MYLES, the President, being in the chair.

Mr. R. L. SWAN read a paper on the Surgical Treatment of Chronic Synovitis. In cases of primary tuberculous synovitis he recommended that the joint should be opened, the fluid evacuated, the synovial membrane irrigated and then thoroughly sterilised with pure carbolic acid, again irrigated with sterilised water, and closed. With proper aseptic precautions he looked on the operation as the best treatment for chronic hydrops articuli of the knee. Rightly carried out the operation placed the synovial membrane in a condition to return to its normal functional activity and the patient recovered a useful limb. He illustrated his paper by the *history of two successful cases. He had not found carbolic* acid the dangerous bactericide that some said it was. He in no way wished to be understood as advocating the operation for disease of the joint complicated with disease of the osseous tissues or cartilage. The operation was intended to place the synovial membrane of the joint in a condition favourable for its recovery.—The PRESIDENT said that in the majority of cases the pathological lesion consisted in pedunculated growths commencing from the alar ligaments. If on opening the joint, especially in children, he found the synovial membranes to be tuberculous, he recommended that they should be dissected out, a procedure which he believed led to recovery.—Mr. E. H. TAYLOR thought that free swabbing with strong carbolic acid devitalised the synovial membranes and the cartilage and left them a prey to the tubercle bacilli in their vicinity. He looked on the method suggested as one not well calculated to give good results in hydrops articuli; the wound healed, but after a little time the limb became shorter and often flexed. There was not true ankylosis. He recommended that the hyaline cartilage should be shaved off the bone and the raw osseous surfaces joined, ensuring a sound limb.—Mr. JOHNSON said that he had under his care a man with hydrops articuli which was benefited for a time under the treatment by rest, but the swelling did not wholly disappear. He opened the joint, irrigated it, and closed it. The fluid removed—about 18 ounces—was highly albuminous. The synovial membrane contained bacilli in large numbers. The incisions, one on each side of, and parallel to, the patellar tendon, healed quickly and well; but they broke down in a week, and not long afterwards the patient developed tuberculous meningitis from which he died.—Mr. H. G. CROLY, Mr. R. F. TOBIN, Dr. W. S. HAUGHTON, and others also took part in the discussion.

Mr. T. E. GORDON read a paper on a successful case of Pylorectomy. The patient, who was 43 years of age, was admitted to the Adelaide Hospital for an abdominal tumour, and on April 2nd, 1901, Mr. Gordon performed the first step in a Roux's operation. The patient made a good recovery with little or no shock. 25 days afterwards the second stage of the operation was *completed by the removal of the pylorus* and about half of the stomach. The intestinal and gastric wounds were sutured with silk, a gauze drain was left in the area of operation, and the wound was closed. The operation occupied one and three-quarter hours. The growth was found to be a columnar-celled cancer. For some days the patient remained in a precarious condition, with a temperature of 102° F. and a pulse of 160. At the end of a week the food was increased in amount and the patient made a good and quick recovery. Mr. Gordon afterwards considered the legitimacy of the operation of pylorectomy, and concluded that in a favourable subject Roux's operation was called for.—The PRESIDENT congratulated Mr. Gordon on the first successful pylorectomy performed in Dublin. In one of his cases he cut down on the stomach with the intention of performing a pylorectomy, but found so much thickening of the gastric walls with what he and his friends thought was cancer that he returned the stomach unopened to the abdomen, and the woman is to-day, after some years, alive and well.—Mr. SWAN also congratulated Mr. Gordon on his great success.

Mr. CROLY showed a case of Amputation at the Hip-joint and a case of Ligation of the External Iliac Artery for Ilio-femoral Aneurysm.

Mr. TOBIN showed a patient, aged 80 years, from whom the Prostate was removed by Enucleation.

---

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on Jan. 19th, Mr. A. H. Tubby being in the chair.—Dr. George Carpenter showed a case of Paroxysmal Hæmoglobinuria in a female child, aged three years. An infant sister had been treated at the hospital for congenital syphilis, but the patient showed no signs of that disorder.—Dr. Charles Macalister (Liverpool) suggested that absorption from the nasal discharge, from which the child suffered, might be responsible for the condition.—Dr. G. A. Sutherland called attention to the presence of oxalates in the urine of such cases.—Dr. L. G. Guthrie spoke of two sisters who developed hæmoglobinuria and who were undoubtedly syphilitic.—Dr. Carpenter, in reply, remarked on experiments showing the immediate destructive action of cold on the red blood corpuscles of such cases when topically applied.—Dr. Carpenter *read notes of a case of Suprarenal Sarcoma in a boy, aged* two and a half years, in which the organs were demonstrated by Dr. D. N. Nabarro who had conducted the necropsy. The right kidney was invaded secondarily by the new growth and the left had become hydronephrotic from pressure on its ureter. The mesenteric and pelvic glands were secondarily invaded and some glands under the sterno-mastoid subsequently. The case in its clinical aspect was not unlike tuberculous peritonitis, but the injection of tuberculin gave negative results and confirmed the original opinion.—Mr. Tubby and Mr. Clement Lucas drew attention to the hopelessness of surgical interference in the large majority of cases of renal sarcoma.—Dr. E. Cautley looked upon it as a case of extra-renal sarcoma, with secondary renal attachment, and inquired as to secondary deposits in the skin.—Dr. Carpenter, in reply, said there were no secondary cutaneous deposits. He did not consider it a case for operation, and that opinion was borne out by the post-mortem examination.—Mr. Clement Lucas showed a case of Traumatic Chorea and Musculo-Spiral Paralysis complicating a fracture of the *upper third of the humerus in a girl, aged 11 years.* The chorea developed within half an hour of the injury and was not associated with heart disease or a rheumatic history. The musculo-spiral paralysis was believed to be caused by the callus resulting from movement during repair, and it was proposed to cut down on the seat of fracture and relieve the nerve from pressure. Another interesting point in the case was an abnormal growth of hair on the lower third of the arm and dorsal aspect of the forearm corresponding to the skin supplied by the injured nerve.—Dr. Frederick Taylor asked whether a recent attack of any infectious disorder could be negatived and whether it was certain that there were no choreic movements prior to the accident. He referred to the obscurity surrounding the relationship of chorea to the emotions and shock. How did the traumatism operate? Through the central nervous system, the nerve of the limb, or by the production of shock?—Mr. G. Pernet, Mr. F. Jaffrey, and Dr. Carpenter joined in the discussion and Mr. Clement Lucas replied.—Mr. Tubby showed several cases of Paralytic Talipes Calcaneo-valgus, Equino-valgus, and Equino-varus which had been treated by muscle-grafting. In some of the cases, especially those of calcaneo-valgus, the results were good, also in two of the cases of equino-varus. But the cases of equino-valgus were not so striking, although the improvement was very considerable. In his remarks on the operative procedures which had been alluded to Mr. Tubby said that paralytic cases might be divided for purposes of treatment into three classes: (1) those in which a single muscle or a single group of muscles were affected, and these were capable of satisfactory treatment by tenotomy; (2) those in which at least two groups of muscles were paralysed, and these were fit subjects for muscle-grafting; and (3) those severe cases in which all

Dr. H. S. Wilson showed some Gelatin-stab Cultures of Anthrax and described the conditions under which the characteristic "inverted fir-tree" or arborescent appearance of stab-cultures of the bacillus were best produced. He had made a few gelatin-stabs under varying conditions of medium, of bacillus, &c. Three strengths of gelatin had been used—5 per cent., 7 per cent , and 10 per cent. Two agar-cultures of anthrax obtained from the blood of an inoculated guinea-pig a few minutes after death were grown at 37° C., one for 20 hours and the other for about 70 hours. The 20 hours' culture was seen on microscopical examination to consist mainly of bacilli, whereas the 70 hours' growth consisted almost entirely of free spores. The stab-cultures were grown for eight or nine days at from 18° to 20° C. and then fixed with formalin vapour. The following results were obtained. 1. *10 per cent. gelatin.*—(*a*) Bacilli: liquefaction cup and streak, but no arborescence; and (*b*) spores: liquefaction cup and streak, but no arborescence. 2. *7 per cent gelatin.*—(*a*) Bacilli: liquefaction cup and streak with slight arborescence. (*b*) Spores: no liquefaction cup, but a streak with well-marked arborescent growth. 3. *5 per cent. gelatin.*—(*a*) Bacilli: liquefaction cup and an arborescence better marked than in the case of the 7 per cent. gelatin. (*b*) Spores: no liquefaction cup, but a very fine arborescent growth. In addition to the above, stab-cultures were made in 5 per cent. and 7 per cent. gelatin from bacilli and spores, and were grown in an atmosphere free from oxygen by Buchner's method. In no case was there any liquefaction or any attempt at arborescence. The point therefore, to which he called attention was that to produce the anthrax "fir-tree" it was useless to make stab-cultures in 10 per cent. gelatin, the strength generally employed in laboratories, and the best strength to use was 5 per cent., and apparently a freely sporing culture gave more satisfactory results than did one containing few spores.

---

## LIVERPOOL MEDICAL INSTITUTION.

*Gall-stones with Chronic Intestinal Obstruction.—Intestinal Anastomosis – Physics of the Mitral Regurgitant Murmur.—The Treatment of Cancerous Affections of the Skin by means of X Rays.*

A meeting of this society was held on Jan 30th, Mr. Rushton Parker, the President, being in the chair.

Dr. A. C. Wilson described a case of Gall-stones with Chronic Intestinal Obstruction in which many diagnoses had been given by various physicians in Liverpool and London. Eventually an exploratory operation revealed gall-stones in the gall-bladder and duct, which were removed, also a curious mass in the intestine which was not dealt with.—Mr. R. W. Murray described the operation which he had performed in Dr Wilson's case. He believed the lump in the intestine to be an impacted gall-stone. In order to deal satisfactorily with this, he thought that it would be necessary to short-circuit the gut, and would not advise further operation unless the suffering of the patient became unbearable.—The President, Dr. W Macfie Campbell, and Dr. F. A. Gill commented upon the case, and Dr. Wilson replied.

Mr. Murray exhibited a boy, aged 13 years, upon whom he had operated for an Artificial Anus in connexion with the small intestine, complicated with considerable prolapse of the gut. Three years previously the boy had been operated upon for intestinal obstruction, a portion of the small intestine, probably about three feet from the ileo-cæcal valve, being brought to the surface and opened. Prolapse of the bowel resulted, and for three years all fæcal matter escaped from this opening in the small intestine. When first seen by Mr. Murray in May last the child's condition was pitiable; he was wasted and anæmic and he carried his prolapsed gut in a bag attached to his waist. In July Mr. Murray opened the abdomen and attached the working end of the small bowel to the transverse colon, end to end. The large gut was much collapsed, and as it had been lying fallow for three years there was some doubt as to whether it would resume its function. The result, however, was very satisfactory, the bowels acting naturally 48 hours after the operation. The general health and comfort of the patient had greatly improved, although there was still a portion of unused bowel prolapsing from the original wound.

Dr. T. R. Bradshaw read a paper on the Physics of the Mitral Regurgitant Murmur. He said that hitherto no thoroughly satisfactory explanation was forthcoming of the fact that the murmur was heard most plainly at the apex of the left ventricle. He suggested that it was brought about in the following way. The fluid vein in the left auricle set up sonorous vibrations in the still parts of the blood behind the mitral valve. The valve being a thin membrane capable of vibrating transmitted these vibrations to the blood in the ventricle, which conducted them to the apex, the part nearest to the chest wall. He was making experiments with models to ascertain how far this kind of transmission was possible, but so far he had not succeeded in exactly reproducing the conditions artificially as the construction of such a model involved considerable mechanical difficulties.—Dr. J. Barr spoke and Dr. Bradshaw replied.

Dr. G. G. Stopford Taylor read a paper on the Treatment of Cancerous Affections of the Skin by means of the X Rays, illustrating his remarks by lantern slides and patients. Case 1.—This was a case of rodent ulcer involving the right side of the nose, the lacrymal canals, and the eyelids in a patient, aged 82 years. Case 2.—This was a case of rodent ulcer on the left cheek, implicating the outer canthus and the eyelids in a patient, aged 64 years. Case 3 was a case of epithelioma on lupus erythematosus affecting the whole surface of the nose in a patient, aged 59 years. Microscopical confirmation of the diagnosis was obtained. Scraping, followed by x-ray applications, was the treatment carried out. Case 4.—This was a case of a large rodent ulcer of the left side of the scalp and pericranium in a patient, aged 78 years. The foregoing cases were of such a nature as to be beyond operative interference or relief by any other known method. The treatment in the first three cases resulted in complete healing of the ulcerated surfaces, with the formation of the most perfect scar tissue and the disappearance of all traces of the disease. In the fourth case, as the pericranium was involved, only partial healing took place, but the wearying pain which usually attended rodent ulceration was much relieved. As a result of the treatment Dr. Taylor arrived at the following conclusions: (1) that the rays were especially indicated in all inoperable cases of cancer of the skin; (2) that the best results were obtained when the disease was confined entirely to the soft parts; (3) that owing to the complete relief of pain and the superior cosmetic result obtained patients too readily assumed that they were well and neglected to attend, and hence recurrence might occur from failure to complete the treatment; and (4) that the use of x rays was no obstacle but a valuable aid to other methods.—Dr. A. N. Walker thought that the action of x rays on rodent ulcer was not due to their escharotic power, but to some influence which, as it were, turned the scale of growth in favour of the healthy tissues, thereby enabling them to destroy and to absorb the malignant cells. In cases treated by the x rays at the Liverpool Northern Hospital he had noticed that the rolled edge remained in the skin after the ulcer had healed and then gradually disappeared, and in one case in particular of recurrence in which further operation was refused the skin was never broken, but the new growth slowly became absorbed under the influence of the rays.—Dr. A. G. Gullan congratulated Dr. Taylor on the cases, and noted especially the excellent supple character of the skin and the splendid condition of the scar tissue.—Dr. Leslie Roberts said that the x rays were being used for all sorts of cutaneous diseases. There was a want of precision in these experiments which was perhaps unavoidable owing to their ignorance of the nature of the force with which they were dealing. But they could not doubt that in the end all this promiscuous experimenting would lead to the discovery of some definite principles which would serve to guide the judgment in the selection of cases for treatment. He believed that the effects on the tissues of the skin of the x rays were, broadly speaking, of two orders—(1) those of a kind analogous to *burning;* and (2) *specific* effects. Roentgen rays appeared to exert a specific action in degenerative epithelium. The growth of hair, nails, and the horny cuticle were rapidly affected, and all these were forms of physiological degenerative epithelium. Rodent ulcer was a purely epithelial disease, and there could be no question that the rays caused a dissolution of the new cell growth. The same was true of epithelioma and possibly, to some extent, of other forms of cancer. It was much to be regretted that they did not possess exact information as to the microscopical condition of the scar of rodent ulcer after healing by x rays The remedial a woman, aged 37 years, the subject of Diffuse Symmetrical Scleroderma. It affected the skin of the face, neck, thorax, and to a less extent the upper extremities. It came on about six months ago and reached its maximum intensity in five months, since which time it had improved.—Mr. F. Marsh showed a case of Carcinoma of the Sigmoid Flexure in a boy, aged 15 years, who was admitted into the Queen's Hospital, Birmingham, on June 26th, 1901, for pain in the epigastrium and passing of blood with the fæces. The passing of blood began six months prior to his admission. The pain, which was intermittent and referred to the epigastrium, only commenced a month before. Per rectum an indistinct fulness could be felt to the left in the recto-vesical pouch. Blood and mucus followed the withdrawal of the finger. On July 5th a median incision was made and a growth was found in the lower three inches of the sigmoid. The growth was excised with a margin of healthy bowel, some enlarged mesenteric glands were removed, and with considerable difficulty the two ends of the intestine, the middle of the sigmoid, and the upper end of the rectum were joined as accurately as the position of the parts would allow with Lembert sutures. A good recovery was made, the bowels acted regularly without difficulty, and the boy went home well on August 7th. Microscopical examination showed that the growth was a columnar carcinoma. The subsequent history, however, pointed to recurrence, as the brother of the boy reported some four months after the operation that there was a return of blood in the fæces, but Mr. Marsh had not had an opportunity of examining him.—Mr. Christopher Martin showed a Kidney removed on Feb. 11th for Calculous Pyonephrosis from a woman, aged 40 years. The patient bore the operation well and made an uninterrupted recovery.—Mr. J. F. Hall-Edwards read a paper, illustrated by lantern slides, on Experiences with the Imperial Yeomanry Hospital in South Africa.

# Reviews and Notices of Books.

*The Healing of Nerves* By CHARLES A. BALLANCE, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to St. Thomas's Hospital; and PURVES STEWART, M.A., M.D. Edin., Assistant Physician to the Westminster Hospital. Illustrated by 16 Plates and one Figure in the Text. London: Macmillan and Co., Limited. 1902. 4to, pp. 112. Price 12*s.* 6*d.*

IN the preface to this treatise the authors state that most of the work was completed by the end of 1899, but the absence of Mr. Ballance at the South African war for more than a year has delayed its publication until the present date. The subject of the volume is one of great interest and has attracted the attention of many observers. The experiments required are not difficult to perform, and they can be practised whilst the animal is under chloroform; but the subsequent microscopical investigation demands a thorough knowledge of the modern methods of staining and mounting, and Mr. Ballance has been fortunate, as he himself points out, in obtaining the assistance of so able a coadjutor as Dr. J. Purves Stewart. The animals on which experiments were made were monkeys, dogs, and cats, and the points which the authors proposed to investigate were the following:—the process of degeneration in a peripheral nerve after injury both without and with immediate suture of the two ends; the process of regeneration in a divided nerve-trunk which has been divided and reunited by suture; the process of regeneration, if any, in the distal segment of a divided nerve, the cut ends of which have not been reunited by suture; and lastly, the changes which occur in nerve grafts. The literature of the regeneration of nerves after injury and a good historical *résumé* and bibliography will be found appended to an article published in 1892 by Professor W. H. Howell and Dr. G. C Huber, in the *Journal of Physiology*, and to articles by Galeotti and Levi in "Ziegler's Beitrage" for 1895 and by Dr. Kennedy in the "Philosophical Transactions" for 1897. On the strength of statements made by Dr. Waller, Professor Ranvier, Professor Kölliker, and Professor His, it has been generally accepted that after division of a nerve new axis cylinders are developed in the form of outgrowths from the axis cylinders in the central segment which, inclosing the medullary sheaths of the distal segment, replace the old axis cylinders which have undergone degeneration. Another view, however, has been advanced which the authors term the "peripheral" theory and to which they give their entire adhesion. According to this the peripheral segments of the cut fibres undergo complete degeneration whilst new fibres in the distal segment—axis cylinders, medullary sheaths, and neurilemmata alike—are formed from pre-existing cells in the distal segment itself, and after their formation become attached to those of the central segment, thereby restoring the conductivity of the nerve-fibre. A small portion of the proximal segments of the cut fibres undergoes degeneration, but this process does not extend to any considerable distance up the nerves towards the cells which form their trophic centres. The successive changes that take place in the process of degeneration have been very carefully worked out by the authors and constitute an interesting history. Within six hours after the initial blood extravasation consequent on the cut an invasion of leucocytes takes place, reaching its maximum about the eighteenth hour. After three days the leucocytes are gradually and largely replaced by connective-tissue cells. These begin to proliferate and on the fourth day indent the fatty substance of the myelin sheaths and then absorb both sheaths and axis cylinders, the whole process occupying several weeks. In the meanwhile, commencing about the second day, the neurilemma cells proliferate, the young cells sending forth fine protoplasmic processes from their extremities in the direction of the original nerve. The smaller nerves resist the degenerative process longer than the larger ones. In the process of regeneration the proximal extremity of the cut nerves exhibits at a very early period—that is to say, within 24 hours—a primitive end-bulb, produced by the curling up of the loose ends of the divided fibres. This acts as a scaffold on which the permanent end-bulb is deposited. The earliest signs of regeneration in the distal segments of the cut nerves occur at the end of three weeks; numerous longitudinal "spider cells" appear in the distal segment and in the intermediate scar tissue which shoot out young beaded axis cylinders from their opposite poles. These are new axons which overlap and coalesce with one another. New medullary sheaths then appear inclosing the axons about the fourth week, and gradually the regeneration becomes complete and the cut nerve functionally active. The regeneration of a cut nerve is not therefore affected by the growth of the proximal extremities of the axis cylinders, but is accomplished by the development from longitudinal chains of cells of axons which fuse together and become inclosed in medullary sheaths. The treatise, though short, is well deserving of attentive study.

*Text-book of Pharmacology and Therapeutics.* Edited by W. HALE WHITE, M.D., F.R.C.P. Lond., Physician to, and Lecturer on Medicine at, Guy's Hospital, London. London and Edinburgh: Young J. Pentland. 1901. Pp. viii.-1040.

THE title of this work accurately describes what manner of book it is and implies what it is not. Here we find no pharmacopœia or materia medica and no description of universal, but only of medical, therapeutics—no book for students preparing for examination, but a standard work of reference for the library of the practitioner. Handicapped as pharmacy in England still is by reason of the lack of a universal system of weights and measures, it has been found necessary to use the English system for clinical descriptions and directions while the laboratory details are given in the decimal system.

the muscles around a limb were useless, and for these arthrodesis was recommended. After speaking of the limitations of muscle-grafting and indicating its scope, and pointing out that as there was a diminution of power applicable to a given joint the best results could not be perfect, Mr. Tubby yet thought that muscle-grafting was a scientific and practical procedure, for it distributed what voluntary power was left around an articulation and so it became well-balanced, although too often weak. The indications and methods of operating in arthrodesis were then alluded to and three cases were shown. A case of infantile spastic paralysis affecting the upper extremity was brought forward in which considerable improvement had been obtained by converting the pronator radii teres into a supinator, and by section of the flexor carpi radialis the patient now had the power of voluntary but partial supination of the forearm. The method adopted was fully described in the *British Medical Journal* of Sept. 7th, 1901, and from an experience of six cases Mr. Tubby thought the operation promised well.—Mr. Clement Lucas and Dr. A. E. Sansom spoke of the value of Mr. Tubby's suggestions, and Mr. Tubby replied.—Mr. Walter Edmunds and Dr. Carpenter showed a case of Myositis Ossificans in a female, aged four years, one of a family of eight. The disorder had been noticed six months and recently had rapidly advanced. The affected muscles were in parts infiltrated and in others displayed bony plates. There was fusion of two phalanges of the great toes, a condition which had been recognised as occurring in these cases. Microscopical examination of a portion of an infiltrated muscle showed fibro-nuclear tissue alone.—Dr. W. A. Milligan read notes on a case of Contracted Granular Kidney in a boy, aged seven years. The chief symptoms were pallor, wasting, headache, and polyuria. The heart was slightly hypertrophied, the skin was bronzed, and the urine was of low specific gravity and albuminous. Later the patient developed albuminuric retinitis, and epistaxis and cutaneous hæmorrhages occurred. Four weeks before death the heart began to fail, the extremities became dropsical, giving place to general anasarca with anuria, and the child died comatose. The kidneys, macroscopical and microscopical, were typical of the condition.—Dr. Carpenter inquired as to a history of syphilis in the case and said that he had not yet detected albuminuric retinitis in cases of contracted granular kidney in children; but he had seen that condition in a child, aged eight years, who suffered from a large white kidney which was verified post mortem.—Dr. Sansom regarded it as one of typical interstitial nephritis, but thought that acute parenchymatous nephritis had been grafted on it.—Mr. Sydney Stephenson thought it quite possible that retinitis might be as common in interstitial nephritis in children as it was relatively in that disorder in adults. His own experience had furnished him with two such instances, the latter of them two days since.—Mr. Stephenson read (for Dr. Lewis Marshall of Nottingham) notes on a case of Thyroid Dislocation of the Hip in a child, aged nine years, of four months' duration, confirmed by x rays. There were two points worthy of note: a previous synovitis of the hip-joint had existed and reduction was quite easily effected by manipulation.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 21st, Mr. P. E. Miall being in the chair.—Cases and specimens were shown by Mr. R. Mercer, Dr. H. J. Campbell, Dr. B. H. Slater, and Dr. R. H. Crowley.—Dr. Nicholson Dobie read notes on a case of Distension and Hernia of the Gall-bladder. The patient was a woman, aged 60 years, who for two years had complained of pain in the umbilical region when she was moving about. There was no pain when she was at rest in bed. For about 12 months she had noticed a lump in the body. There was no history of jaundice. Examination of the abdomen showed a large ventral hernia in the middle line below the umbilicus. The hernia was reducible easily and it contained a tumour which when returned to the abdominal cavity could be moved about freely. The tumour was tense and fluctuating and was of about the size of a fœtal head at full term. On the right side of the tumour was a hard projection one and a half inches long and of the size of three fingers. On Dec. 4th, 1901, the abdomen was opened in the middle line below the umbilicus. The tumour was found to be a greatly distended gall-bladder with thickened and congested walls. There was no adhesion. In a pouch on the right side was a large gall-stone cylindrical in shape and weighing eight and a half drachms. The gall-bladder was opened, the stone was removed, and the gall-bladder was then stitched to the upper end of the abdominal incision and the rest of the wound closed. The wound healed by first intention except for the biliary fistula. On Dec. 27th the patient had an attack of right hemiplegia with complete loss of speech.—Mr. Mercer read the notes on a case of Pyloric Obstruction—Gastro-jejunostomy. The patient was a woman, aged 45 years. In March, 1899, oöphorectomy had been performed for dysmenorrhœa and ovarian neuralgia. In September, 1899, symptoms of gastric disturbance began with pain and vomiting. Blood was present in the vomit on one occasion. Notwithstanding treatment by rest in bed, dieting, and gastric lavage, relief was never more than temporary, and as she was becoming more and more emaciated and weak operative measures were advised. She was admitted to a hospital and the abdomen was opened in January, 1901. A band was found stretching from the greater curvature of the stomach near the pylorus to the scar of the previous operation. This was divided and in addition the pylorus was stretched by the fingers, the stomach wall being invaginated into it. For three months the patient did well but then the old symptoms began to return, and by August she had fallen back to much the same condition as before and appeared to be dying slowly from starvation. At the patient's request a further operation was undertaken by Mr. Mercer at home in October, 1901. On opening the abdominal cavity the transverse colon was found to be adherent to the scar and the intestines were matted together; after some difficulty the jejunum was brought up into the wound and united to the posterior portion of the stomach. The pylorus was embedded in a mass of adherent intestines and was not seen. The shock after the operation was not severe, but there was very persistent vomiting which was stercoraceous on the morning of the third day. The stomach was washed out with permanganate of potash solution and a turpentine enema administered. The vomiting now ceased and the patient was able to take nourishment. A month after the operation she was taking solid food and was rapidly regaining her strength and weight. She did well for a time, but recently (January, 1902) the old symptoms of pain and vomiting had returned.—Dr. C. F. M. Althorp read notes on three cases of New Growth in the Large Intestine.—Mr. J. Basil Hall read a paper entitled "Some Observations on Dilatation of the Stomach and a Modification of Posterior Gastro-jejunostomy," illustrated by five cases.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Jan. 21st, Dr. A. Wahltuch being in the chair.—Mr. J. Howson Ray related a case of Strangulated Femoral Hernia occurring in a man, aged 53 years, where the sac was found to contain about three drachms of foul-smelling pus and a gangrenous loop of small intestine which had already given way. The symptoms were masked by alcoholic mania. The patient was sent into the Salford Royal Hospital by Mr. J. Cantley of Higher Broughton, and was operated upon by Mr. Ray about half an hour after admission. The gangrenous bowel—about three and a half inches long—was excised and the ends of the gut were united by continuous catgut sutures, including all the coats of the intestine, whilst Lembert's sutures of fine silk were used in two layers outside. No button or bobbin was employed. The sac was removed and a gauze drain was left for a few days with a small-sized drainage-tube just entering the peritoneum. Feeding was entirely per rectum for the first week. On the eighth day there was some fæcal matter noticed about the wound and for a week longer fæces discharged at the groin as well as per rectum. In the course of the fifth week the wound had entirely healed and the patient's mind was practically clear. He left the hospital quite well eight weeks after admission. The patient was shown to the meeting, as also the specimen removed.—Mr. J. E. Platt gave a demonstration on Diseases of the Tongue and showed cases of smoker's patches, leukoplakia, atrophy of papillæ, erythema migrans, lichen planus, secondary and tertiary syphilitic affections, tuberculous ulcer, dental ulcer, nævoid papilloma, and epithelioma. He advocated the use of ointments with a basis of vaseline and lanolin, as recommended by Mr. H. T. Butlin, for the treatment of certain affections of the tongue, several of the cases having derived great benefit from their application.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on Jan. 22nd, Mr. Arthur Oakes, the President, being in the chair.—Mr. W. F. Haslam showed was thus able to trace the gastric movements with great precision. The curious constrictions that occur and the march of the peristaltic waves are very distinctly shown, and they serve to modify the views generally accepted on the authority of Dr. Beaumont and Dr. Brinton. Two remarkable cases of ablation of the whole stomach, with preservation of life for a considerable period, are recorded. The whole chapter on Digestion, without containing much *that is novel, gives a good résumé of our present knowledge* of that function. The chapter on Voice and Speech, with the illustrative photographs of the larynx, chiefly giving Professor French's views, is highly instructive.

The section on the Circulation is the least satisfactory one in the book. We are unable to find any account of the nerves distributed to the heart except a few lines under the heads of the Medulla Oblongata and Spinal Cord. It is true that our knowledge of the relations of the nervous system to the heart is still very imperfect, and that much of what is known admits of more than one explanation, but this hardly justifies its almost entire omission in such a treatise as this. Again, Professor Raymond can hardly have seen Stephen Hale's "Statical Essays" or he would not have named him "Stephen Hall." His "classic experiment" was originally performed *in 1702, and not in 1727, and he did not introduce* a goose-quill into the femoral artery of a horse, but, as he says very explicitly, "a *brass* pipe whose bore was one-sixth of an inch in diameter, and to that, by means of another brass pipe which was fitly adapted to it," he fixed "a glass tube of nearly the same diameter, which was nine feet in length." Here and there we have noticed a few slips of the pen—as, for example, that noted above, and "Halle," on p. 357, which is a misprint for *Haller*. The explanation which Professor Raymond gives of the fact that the moon seems larger to an observer when near the horizon than when near the zenith is not satisfactory. "Near the horizon," he says, "we have terrestrial objects to compare it with, while when in the zenith there is nothing with which to compare it." But it *may be said that the moon looks large when rising on* Salisbury Plain, on which there is no conspicuous terrestrial object with which it can be compared, and looks small at its zenith when close to the vane of the spire of Salisbury Cathedral, the size and distance of which are well known. It is probably an affair of refraction. The book is well got up and well printed, and may be regarded as a trustworthy guide for the student and a useful work of reference for the general practitioner. The illustrations are numerous and are well executed.

---

*The Sanitary Inspector's Handbook.* By ALBERT TAYLOR, Member of the Sanitary Institute; Holder of the Inspector of Nuisances Certificate of the Sanitary Institute; Demonstrator to the Students of the Sanitary Institute; Sanitary Inspector to the City of Westminster; late Chief Sanitary Inspector to the Vestry of St. George, Hanover-square, London; formerly Chief Inspector of Nuisances, Wigan; and Sanitary Inspector of Wallasey. Third edition. London: H. K. Lewis. 1901. Pp. 408 Price 6s.

THIS book is intended chiefly for the use of students preparing for the various examinations in sanitary subjects which are held to test the knowledge of those who wish to become sanitary inspectors in England and Scotland. The qualifications of the author to write on the subject are fully given on the title-page and are duly quoted above and the fact that the book has already passed through two editions proves that the work has been appreciated.

The amount of information which a well-qualified sanitary inspector must possess on a great variety of subjects appears at first sight to be almost appalling. He should have a general knowledge of the provisions of the Public Health Acts and a practical knowledge of what constitutes a nuisance from a legal point of view, and should understand clearly the exact procedure to be adopted in serving the statutory notices before taking the legal proceedings which are occasionally necessary. Order, method, and accuracy are essential for the due performance of his duties, and without the exercise of these qualities his official books and diary would be worse than useless. A practical knowledge of drainage and of water-closets is essential, *and the testing of drains is an important part of* his daily work. He will do well to possess a general knowledge of the problems connected with water-supply and of the laws which bear upon it, and it is essential that he shall be able to collect a sample of water *secundum artem* for the use of an analyst. While a knowledge of infectious disease is advantageous a practical knowledge of the methods of disinfection is necessary. A sanitary inspector should also understand the theory of ventilation and be capable of making accurate measurements of cubic spaces. It is not likely that he will have to deal frequently with undecagons and duodecagons, but he will find in Mr. Taylor's book (at page 250) information as to how he should proceed in such circumstances and a table bearing on the subject having figures which extend to seven *decimal places An ideal sanitary inspector should under*stand the law on meat inspection and the by-laws and regulations which are in force regarding it, and should have a knowledge of the normal appearance and of the various morbid appearances presented by the organs of all the animals which are used as food by man. Slaughter-houses come under his supervision, lodging-houses give him trouble, and his duties in regard to canal-boats are not always easy of execution The supervision of the sanitation of factories and workshops falls under his care, and his duties in connexion with dairies, cowsheds, and milkshops are by no means light The due execution of the provisions of the Sale of Food and Drugs and Margarine Acts is an onerous responsibility, especially as the sanitary inspector has no fixity of tenure and his appointment is often made by gentlemen interested in the sale of food. Mr. Taylor's book deals with all the questions mentioned. It should prove useful, not only to those who are, or who wish to become, sanitary inspectors but also to the laymen whose duties as members of municipal bodies necessitate a general knowledge on those sanitary matters over which they exercise authority.

The book on the whole is a good one, but there are a few little things which might with advantage be altered in the next edition. There is no necessity (page 187) to perpetuate the unsavoury opinion of the River Pollution Commissioners that "river water to which sewage gains access" is "palatable." Mr Taylor is also very lax as to his views on the smoke nuisance—a matter with which it may be hoped that the civic authorities of Westminster will deal The book contains one quotation from the work of a metropolitan officer of health which is rather curious. It relates to the evils of overcrowding. Everyone is familiar with the ill-effects of intemperance and other sinful courses as described by sensational writers, but even with these, as a rule, "death ends the scene." This does not appear to be the case in the matter of overcrowding. The ill-effects produced are "pulmonary tuberculosis, continued fever, generally impaired health, a putrid condition of the body, followed by *death, mania, boils*," and *so on*. The idea of having boils after death adds a new terror to overcrowding.

---

## LIBRARY TABLE.

*Diseases of the Nose and Throat.* By J. PRICE-BROWN, M.D., L.R.C.P. Edin., Laryngologist to the Toronto Western Hospital and to the Protestant Orphans' Home. With 159 Engravings and six Coloured Plates. London: Henry Kimpton. 1901. Pp 471. Price 7s. 6d.—This is the first

The authors of the various chapters and sections are 29 in number, and include professors of the University of Michigan and teachers at the colleges of Philadelphia, in addition to members of the staffs of most of the London general hospitals. The classification of the drugs leaves much to be desired from the point of view of the reader who intends steadily to read through the work, but for reference purposes the index to a great extent makes up for shortcomings. For the most part the medicines are grouped according to "their pharmacological affinities, but in some instances the arrangement depends upon the convenience of keeping together several minor drugs described by the same author." The administration of anæsthetics is thoroughly dealt with by Mr. G. Rowell of Guy's Hospital, while the Pharmacology of Chloroform itself is the subject of one of the articles by Dr. J. Rose Bradford and Dr. Leonard Hill, F.R.S. Dr. R. Stockman of Glasgow University deals with opium and quotes Sir George Birdwood on the "opium habit," besides giving a *résumé* of the views of the gentlemen who sat on the Royal Commission on Opium-taking. The important and interesting section on Organo-therapy has been intrusted to Dr. H. W. G. Mackenzie of St. Thomas's Hospital, while the articles on Serum-therapy are from the pen of Dr. J. W. Washbourn of Guy's Hospital. The chapters devoted to Diet occupy 25 pages and contain the views of Dr. Sidney H. C. Martin, F.R.S. There is an excellent and very readable article on the Effects of Rest, Exercise, and Baths on Cases of Chronic Heart Disease. This section will be found of the greatest use to general practitioners, containing as it does a discussion about the Nauheim method of treating the disease.

As the diseases which are giving rise to most investigation, experiment, and discussion at the present day are those due to tuberculous infection, we naturally turn to a book like this to find the fullest and latest authoritative views about the open-air treatment of pulmonary tuberculosis. There is a section devoted to this subject, it is true, but only the main features of the system are dealt with, and those all too briefly. We are of opinion that this article should have been written by a physician who has had many years of practical experience of the system, and that there ought to be more "physiological light" thrown on the *rationale* of the method. "Undoubtedly a great deal of dyspepsia is promoted by an undue quantity of liquid food, and appetite for solid food is proportionately diminished." Theoretically this may be true enough, but the reader who is referring to this subject in this book should read also the views of medical men who have themselves been sufferers from the disease and have recovered. Such practitioners have seen many cases actually undergoing treatment in addition to the knowledge and experience gained *in propriâ personâ*. It is true that the subject is a large one, and will attain considerable proportions in the future. If a medical man in a large practice wishes for up-to-date practical information and advice about the open-air treatment of pulmonary tuberculosis he will do well to look elsewhere for it than in this otherwise excellent work.

---

*Human Physiology, prepared with special reference to Students of Medicine.* By JOSEPH HOWARD RAYMOND, A.M., M.D., Professor of Physiology and Hygiene in the Long Island College Hospital. Second edition, with 443 Illustrations, some of which are coloured, and Four Full-page Lithographic Plates. London and Philadelphia: W. B. Saunders and Co. 1901. 8vo Pp. 668 Price 15*s.* net.

THE domain of physiology is of such wide extent and is so rapidly enlarging that it is not difficult for an author who undertakes to write a treatise upon it to present the more important facts in a novel way and to expatiate upon others that are usually passed over with brevity. At the same time, in any work that proposes to give a *résumé* of physiology in the compass of 600 or 700 pages a large portion of it can only represent facts that are generally accepted and are contained in most of its predecessors. It is convenient, no doubt, for a professor to publish a book devoted to the subject on which he lectures. It brings to a focus his own knowledge, and it enables his class to read up the lecture of the day, and so fulfils its purpose; but as nearly every college professor has written a book of the same kind Professor Raymond can hardly expect that his "Human Physiology" will displace the works of Halliburton, Hall, Howell, Waller, Starling, or Foster on the subject. Still, it is a very creditable performance, and whilst the men attending his lectures will doubtless study it attentively it may well be read with care by those who are in view of any examination on physiology or who wish to get a new reading of familiar physiological facts.

Professor Raymond divides his book into five parts: Histology; Physiological Chemistry; the Nutritive Functions; the Nervous Functions; and the Reproductive Functions. The chapter on Histology is briefly but well given, and the illustrations are excellent. He accepts Schäfer's views of the structure of muscle, but makes no mention of the peculiarities of the smaller vessels. The chapter on Physiological Chemistry contains the facts usually given under this heading and passes by an easy transition into the consideration of Food, under which heading some interesting facts are given. Thus, speaking of sugar, the author quotes a bulletin issued by the United States Department of Agriculture and written by Mary H. Abel. It appears from this that between 7,000,000 and 8,000,000 tons of cane sugar are used annually in the different countries of the world, England consuming in 1895 86 pounds per head: the United States, 64 pounds; and Italy, Greece, and Turkey less than 7 pounds. By a slip of the pen, it is stated that two-thirds of the *cane* sugar now used are derived from the sugar *beet.* We suppose "crystallised" should be substituted for "cane." It is remarkable that the sugar beet of 1806 contained only 6 per cent. of sugar, whilst that of to-day contains 15 per cent. Miss Abel thinks that the Americans use too much sugar in their cuisine, or rather that they use it with too many kinds of food. The daily quantity of sugar that should not be much exceeded is from four to five ounces. Speaking of vegetarian diets he draws attention to a quotation from Gubler made by Dr. Alanus, himself a vegetarian, that vegetable food, being richer in mineral salts than that of animal origin, introduces more of these salts into the blood as a result of which there is a tendency to an atheromatous condition of the arteries. This belief is borne out by the frequency of atheromatous degeneration of the arteries in the rice-eating natives of Bombay and Calcutta. Hence, purely vegetable diet does not appear to be the normal food of man. The rations of soldiers in the United States army and those of the men in the English and German armies are given and are instructively compared. The section on Alcohol is worthy of perusal, as it gives the results of Professor Atwater's experiments, in which two and one-half ounces of pure alcohol were given in divided doses. This quantity is equal to that contained in about three glasses of whisky or in a bottle of claret. The experiments showed that whilst about two parts per cent. were discharged by the several emunctories of the body the rest was consumed or oxidised like any other food and was not different in this respect from fat, starch, or sugar.

The section on the Movements of the Stomach, which in most works on physiology is merely an echo of the observations of Dr. Beaumont on Alexis St. Martin, are diversified here by an account of these movements as observed by Dr. Cannon who experimented upon a cat to which subnitrate of bismuth had been administered. This salt renders the stomach opaque to the Roentgen rays and Dr. Cannon even now have been omitted the student must refer to the larger text-books.

*Pocket Formulary for the Treatment of Disease in Children.* By LUDWIG FREYBERGER, M.D. Vienna, M.R.C.P. Lond., Physician to the St Pancras and Northern Dispensary; late Clinical Assistant, Hospital for Sick Children, Great Ormond-street. Third edition. London: Rebman, Limited. 1901. Pp. 260. Price 7*s.* 6*d.*—The second edition of this useful and well-arranged little volume was favourably reviewed in THE LANCET of Sept. 29th, 1900, p. 948, and we are glad to see that the demand for it has justified the bringing-out of a third edition in a slightly enlarged form. The drugs described are for the most part those of the British Pharmacopœia, but some serviceable additions have been taken from the Pharmacopœia of the British Pharmaceutical Conference, the United States Pharmacopœia, and a few of the continental ones. The arrangement of the drugs being alphabetical is convenient for reference; under each of them the uses, therapeutics, and doses at different ages are given, together with suggestions for flavouring and complete prescriptions, two or more in number. In the appendix there are other alphabetical indexes in which drugs are classified according to their properties—e.g., alterantia, anæsthetica, antacida, &c., and diseases are similarly arranged from Acne to Zymotic Diarrhœa (Cholera infantum). Dr. Freyberger has succeeded in compressing much information into a moderate compass.

"*Who's Who*" *for 1902.* London: Adam and Charles Black. Pp. 1424. Price 5*s.*—"Who's Who" is certainly one of the most useful books of reference that we possess. There are but few changes in the plan of the issue for this year as compared with that for last year, except that the list of those who have received the Victoria Cross, which appeared last year in an incomplete form, has this year been omitted altogether. So have the articles on the Church of England and that on the Church of Rome. Altogether, Part I. has been cut down by 20 pages, and yet the whole book this year consists of 1424 pages, as against 1234 last year. The increase, therefore, must be in the biographies, some of which might very well be cut down. But as a whole the publication is most useful and one to which we constantly have occasion to refer.

*Whitaker's Peerage, 1902.* London: J. Whitaker and Sons, Limited. 1902. Pp. 647. Price 2*s.* 6*d.*—Whitaker is always modest. His book is not only a peerage, but a baronetage, a knightage, a list of Companions of Orders and of bishops, both spiritual peers and others. The Lords of Session are also given The printing, paper, and binding of the book are unexceptionable and the amount of information contained is marvellous. Especially useful are the accounts of branches of the family of a present holder of a title, Altogether an admirable book.

*The Local Government Annual and Official Directory, 1902.* Edited by S. EDGECUMBE ROGERS. London: The *Local Government Journal* Office. Price 1*s.* 6*d.*—This book claims to be "the most complete Local Government Directory." It may be so, but the text is so sandwiched with advertisements that it is the most irritating book of reference which we have ever come across. Such an arrangement of advertisements in a book of reference is unpardonable, and we advise Mr. Rogers to see that in his next edition the advertisements are relegated to their proper place—namely, before and after the text of the book.

*Herbert Fry's Royal Guide to the London Charities.* Edited by JOHN LANE. London: Chatto and Windus. 1902. Pp. 293. Price 1*s* 6*d.*—This little book has reached its thirty-eighth annual issue. We have nothing new to say about it. It will serve a most useful purpose, first as a book of reference for the poor, who are anxious to obtain relief, by telling them where to go; and secondly, for the charitable, by giving them details of various institutions to which their money may profitably be given. The book still contains information about a number of controversial "religious" societies which by no stretch of language can be called "charities." These societies, we notice, do not make any return of "persons benefited," but we cannot think that they should be in a book of this kind at all.

# Looking Back.

FROM

## THE LANCET, *SUNDAY, FEB.* 8, 1824.

WE are perfectly aware that in the history of JONES'S case,[1] which we communicated to the public, there are two defects.—First; the slight account of the man's state previous to the operation, which was owing to the very short notice that was given of it, thereby preventing us from obtaining those particulars which we otherwise should have acquired.—Secondly; what is so properly complained of by our correspondent viz.—the omission of the appearances of the removed limb. This arose from the bone not having been exhibited, a circumstance which we exceedingly regret. No operator should ever omit, in justice to those who are present, and to his own character as a surgeon, to exhibit the parts which are removed, in order that all may see the reasons for which the operation was performed.—In consequence of Sir ASTLEY COOPER having omitted to do this, an impression exists in the minds of some, that he was *not* justified in the course he adopted, *of* removing the limb from the joint. Had the appearances of the bone been shown to the students, the profession would then have had sufficient *data* for judging of the propriety or impropriety of the operation, and the present impression would most probably never have existed.

From the number of operations performed at the Borough hospitals, some persons think that the knife is occasionally resorted to in cases where it might be dispensed with. In answer to this, we would only state at present, that the size of these institutions should be borne in mind; and the celebrity which the surgeons belonging to these institutions, have obtained for their skill in the use of the knife. We must confess, however, that a great rage for operations exists at the Borough; *the pupils are extremely anxious to see them* performed, and the surgeons appear equally anxious to obtain a reputation by performing them. The surgeons and students of surgery, however, should remember that there is something else besides the mere mode of operating—that there is another important point connected with *operative surgery*—the time when operations *should* be performed. To know how to operate well, a man must possess some manual dexterity, and an acquaintance with anatomy; different operations requiring these qualities in a different degree. To know when operations ought to be performed, and when they ought not, requires more extensive attainments, and can only be learnt by those who investigate disease, and *watch its effects with a degree of attention* which few seems disposed to bestow. The principles of medicine must be thoroughly understood. An acquaintance with various remedies, diet and temperature, on various complaints, must also be possessed—knowledge which can only be attained by the most laborious study and diligent observation—To remove a limb, or to come to see it removed, demand little exertion on the part either of the surgeon or student, compared with a patient examination into the nature of the disease, for which the operation is to be performed; and of the chances of amelioration a patient may possess, from the trial of different means on the complaint under which he labours. There are some cases in *which there* cannot exist a doubt as to the propriety of operating; where, on the prompt skill of a surgeon, the life of a patient depends. We do not wish to discourage the performance of operations, when they are necessary; but we make these remarks on account of the misdirection which the minds of the students appear to receive from looking only at the manner in which the operator uses the knife, without ever enquiring into the reasons for which the operation is performed.

---

[1] Vide account of Amputation at the Hip Joint under the heading "Looking Back" in THE LANCET, Jan. 18th, 1902, p. 172. The above editorial observations were elicited by a letter from a correspondent.

Canadian text-book on Diseases of the Nose and Throat, and as such deserves a welcome apart from the merit which it possesses. Dr. Price-Brown tells us that he has been stimulated to publish his work on account of the indifferent knowledge possessed by the profession at large of diseased conditions peculiar to the nose and throat. He says that the book is intended for the use of general practitioners, and that the anatomy of the parts is only touched upon sufficiently to enable the readers to treat such diseases as they meet with in practice. He wisely omits diphtheria from the book as being thoroughly dealt with in works on general medicine. The subject matter is very clearly rendered, and much thought and space have been devoted to treatment, each disease not only having its most approved and useful medicinal remedies enumerated, but carefully selected prescriptions are added, both Dr. Price-Brown's and those of other well-known authorities, though, in common with most transatlantic specialists, oily sprays and nebulæ are more advocated than is the custom here. In discussing the etiology of hypertrophic rhinitis the author suggests that the habit of always putting a child to sleep upon the same side has an influence or tendency to cause this condition. We are doubtful as to the correctness of this observation, especially as deviations of the septum are more commonly towards the left and the side on which most people sleep is the right, and if nasal respiration was conducted in nasally healthy people only through the upper nostril the septum should more often bulge towards the right side. Total removal of the inferior turbinate is condemned in Canada on account of the dry climate. In atrophic rhinitis and naso-pharyngitis the regular use of a post-nasal syringe or spray, in addition to nasal irrigation, is strongly recommended, and Dr. Price-Brown is also in favour of vibratory massage, using a probe covered with cotton-wool soaked in albolene. He believes that there is ample evidence to show that fibrinous rhinitis is a disease distinct from nasal diphtheria and he differentiates between œdematous and vasomotor rhinitis, which seems to be a purely arbitrary separation. We consider that evidence in favour of the separation is indifferent, and we strongly deprecate the home use of solutions of cocaine, which he advocates, as being liable to set up the cocaine habit. The removal of adenoids is not recommended by the author unless the growth is large; for the smaller hypertrophies an alcoholic spray is advised—a form of treatment that appears to be worthy of trial. Dr. Price-Brown's book is one which will be of special value to those in general practice. It is written by one who has had a long experience of general practice with a full knowledge of the special subjects treated of, and we believe it will prove a useful book of reference to busy practitioners. The illustrations, with the exception of some good coloured photographs of sections of the head, are chiefly reproduced from other works.

*Elementary Practical Hygiene.* Section I. By WILLIAM S. FURNEAUX. London, New York, and Bombay: Longmans, Green, and Co. 1901. Pp. 239. 8vo. Illustrated. Price 2*s.* 6*d.*—The grand importance of making the education of the young a preliminary and foundation of their later education is now beginning to be realised in England. People object to more "science" in schools because children are already taught far more than they can truly assimilate and "cramming" has to be resorted to. This is because both parents and ordinary school teachers have so little knowledge of what "science" really is. If they knew what science is they would not sanction for an instant the system of education that so largely prevails among us. With every desire to do justice to the efforts of those who are responsible for the carrying-out of school routine, what better can we say of our expensive educations for the young than that when our boys and girls leave school they have nothing but a mere smattering of a large number of different subjects? To what but widespread ignorance of hygiene and domestic science can we refer the fact that here is a nation with a splendid past, a glorious future before it, and yet a nation with scarcely a healthy family in it? We medical men can vouch for the truth of this statement of universal poor health. A nation, then, that cannot keep itself in good moral and physical health needs knowledge of some sort very badly. And if this is not applied domestic science—the principles of hygiene—what is it? Such a book as that of Mr. W. S. Furneaux is one of those which are beginning to be appreciated as harbingers of the healthier times to which we may surely look forward. The book is interesting, well illustrated, well written, and to be understood of all who are to any extent intelligent. The experiments are all simple and need no expensive apparatus. "Science," people must be taught, is not dry, but interesting, not abstruse, but simple. The book is a really valuable one, and the attention of all schoolmasters, governesses, and parents should be directed to it.

*Index for Surgical Records.* By CHARLES W. CATHCART, F.R.C.S. Eng. and Edin., Surgeon to the Royal Infirmary, Edinburgh. Edinburgh: A. & D. Padon.—We have received from Messrs. A. & D. Padon, of 13, St. Andrew-square, Edinburgh, a specimen of their "Index of Surgical Records," which is an attempt to apply the card system, so much in vogue now in dealing with business documents, to the arrangement of notes of surgical and medical cases. One objection undoubtedly to clinical note-taking is that the recorded observations of the students are seldom of any personal use to them afterwards. Mr. Cathcart would provide the student with an indexing portfolio with 32 pockets, each of which is arranged for the reception of notes concerning a different organ or physiological tissue, pocket 8, for example, being for the eye; pocket 17 for the peritoneum, mesentery, and omentum; and pocket 31 being for the lungs and pleura. A scheme of classification is provided whereby the notes could be best arranged within their separate pockets. Undoubtedly the idea is a good one, and one that might appeal with force to an orderly and ambitious student. With a properly kept portfolio he would be able in a moment to put his hand on the record of all his past experiences.

*The Pocket Gray.* By the late EDWARD COTTERELL, F.R.C.S. Fifth edition, revised by C. H. FAGGE, M.B., M.S. Lond., F.R.C.S. Eng., Senior Demonstrator of Anatomy, Guy's Hospital. London: Baillière, Tindall, and Cox. 1901. Pp. 269, small 8vo. Price 3*s.* 6*d.* net.—The usefulness of this volume in its former editions was not a little impaired by its doubtful accuracy in matters of small detail. Candidates for the Fellowship of the Royal Colleges of Surgeons need to know their minute anatomy very well, and stand in urgent need of a small book which should contain all details without unessential verbiage, yet be thoroughly trustworthy and accurate. Mr. Fagge has set to work to supply students with such a little book, which is still within the limits of a pocket volume and yet will be found to contain all the anatomical knowledge necessary for examination purposes in a concise and categorical form. Here and there in this fifth edition are amplifications of the descriptions of viscera and investing membranes. There is only one actually new departure in this edition and that is a most welcome one—the addition of the action of each individual muscle to its anatomical description. Always held high in the estimation of students, the "Pocket Gray" will soon be considered indispensable, and for those who have completed their dissections there will be no more popular way of refreshing the memory for details than by studying this little book. The additions and alterations that have been made have not added appreciably to its bulk, and for the few important details that indeed relieve the Government of a great and constantly recurring source of anxiety, for it will lessen its responsibility, while from the point of view of the people of London the very fact that the control of the metropolitan water companies rests with a well-qualified Government department is a distinct advantage. There are doubtless some people who profess that popular control necessarily ensures efficiency. Experience does not prove this. *The Government Bill, judged from Mr.* LONG'S exposition of it, and as viewed in the light of a knowledge of the facts, appears at first sight to be an "honest endeavour" to disembarrass the Local Government Board of some of the most useful and the most arduous of its present duties. We are glad that the Bill has at last been introduced, and trust that it will receive the careful consideration which it deserves.

◆

## Suspected Poisoning by Arsenic in Beer at Halifax.

FEW features of the Manchester epidemic of arsenic-poisoning among beer-drinkers were more striking than the occurrence of peripheral neuritis, with or without symptoms specially indicative of its arsenical origin, in persons whose daily dose of arsenic in beer must have been quite small. And this circumstance has given rise to some interesting speculations, well worth pursuing by the aid of experiment, as to whether the toxic action of arsenious acid is enhanced by simultaneous administration of alcohol; or whether, in process of brewing, a compound of arsenic may be formed which has greater toxic properties with respect to nerve-tissue than are possessed by arsenious acid. However this may be, it is certain that the possible danger of small amounts of arsenic in beer cannot be disregarded.

It is now known that glucose and invert sugar are not the only substances used in brewing which are liable to be arsenical. Malt itself, on account of its exposure in the kiln to products of combustion, may contain very appreciable quantities. We have no doubt that brewers as a whole are fully alive to the necessity of exercising the greatest care in the selection of their various materials and in excluding arsenic from their beer, but the evidence given at an inquest held last week by Mr. E. H. HILLS, coroner for Halifax, goes to suggest that the precautions adopted are not invariably efficacious. At this inquest it was stated that samples of beer collected by the coroner's officer from three publicans in Halifax were sent to Mr. A. H. ALLEN, the public analyst of Sheffield, who found in them respectively one-eighteenth, one-twenty-fourth, and one-sixteenth of a grain of arsenic per gallon. Mr. ALLEN, it may be noted, is a member of the joint committee appointed by the Society of Public Analysts and the Chemical Society to examine methods of determining arsenic in beer, and although it appears from a local press report that statements were made on behalf of the brewers that other samples of their beers had been pronounced free from arsenic, there need be no hesitation in accepting Mr. ALLEN'S results in respect of the samples submitted to him. Such quantities of arsenic in beer must, we think, be considered undoubtedly dangerous. In the particular case before the coroner the victim who drank beer represented by the above samples appears to have been an old man who suffered from bronchitis which the jury found to be the cause of death. But on admission to the Halifax Workhouse Hospital he showed marked pigmentation, foot-drop, extreme tenderness of the muscles of the calf, and running at the eyes—symptoms which, as Dr. E. S. REYNOLDS and others have shown, were frequently met with during the Manchester outbreak. After death, which resulted from cardiac failure, a post-mortem examination was made and samples of the viscera were sent to Mr. ALLEN who found arsenic in the liver to the extent of about one-fortieth of a grain—a result not unlike those obtained in fatal cases during the Manchester outbreak. Having regard to these facts we are in complete agreement with the observation of the coroner that Dr. J. F. HODGSON, the resident medical officer of the workhouse hospital, acted rightly in reporting the case in order that an inquest might be held.

We publish on p. 399 an interesting letter from Dr. HODGSON with reference to the little outbreak in the hospital. For in addition to the fatal case, other patients presenting symptoms suggestive of poisoning by arsenic in beer have within the last few weeks been admitted into the same workhouse hospital, and arsenic has been recovered from the urine in certain of these cases. Although thus far these suspicious cases are few, it seems important, in view of recent experience, that they should be made the subject of official inquiry. The Arsenical Poisoning Commission appears to have been represented at the inquest, and it is to be hoped that the facts will be fully ascertained and laid before that body. In its first report the Commission advised certain precautions by which arsenic could be kept out of beer, and recommended as a provisional safeguard that standard tests for arsenic in ingredients of beer should be laid down by the Board of Inland Revenue and should be made compulsory at breweries. These tests, however, have not yet been promulgated, and the occurrence at Halifax suggests that the presence of arsenic in beer may still be detected at the bedside earlier than in the laboratory. Having regard to this possibility it seems very desirable that the occurrence in relation to beer of alcoholic neuritis, or other forms of illness which suggest the possibility of arsenic, should continue to be closely watched by medical officers of hospitals and workhouse infirmaries and by the public authorities concerned. We congratulate Dr. HODGSON on having been alive to the situation.

## The Reform of the Army Medical Service.

IT may be in the recollection of our readers that a communication from Professor T. CLIFFORD ALLBUTT upon the causes of the neglect of the Army Medical Service among certain university students, and upon the means proposed to increase its attractions, was published in the *Times* in November last. In a subsequent letter which appeared in that journal on Feb. 3rd Professor ALLBUTT returns to the subject, and, in ratification of the correctness of the impressions and opinions that he had previously expressed—to the effect that the lack of scientific spirit and method in the service is the main cause of the

THE LANCET.

*LONDON: SATURDAY, FEBRUARY 8, 1902*

# The Metropolitan Water-supply.

ON Jan. 31st Mr. LONG, the President of the Local Government Board, introduced into Parliament the Government "Bill for establishing a Water Board to manage the supply of water within London and certain adjoining districts, for transferring to the Water Board the undertakings of the metropolitan water companies, and for other purposes connected therewith." An abstract of this Bill will be found on page 392. In the course of a very able speech Mr. LONG emphasised a point on which we have frequently had to insist—the fact that the question of the water-supply of London has no relation to party politics. "There is a general and widespread desire," said the President of the Local Government Board, "that some reasonable scheme should be produced which will remove this question of the administration of the London water-supply from the region of political controversy." Fortunately for the Government Mr. LONG has been impressed with the difficulties of the subject with which it has been his fate to deal and his speech shows that he has bestowed time and thought upon the matter. We can only give within the limits of this article a brief outline of the manner in which Mr. LONG proposes that the London water question shall be "finally settled"; but readers of THE LANCET have considerable knowledge of the various points of a most difficult and delicate question, so that they will be able in a great measure to complete the picture for themselves.

A Water Board is to be established to regulate the supply of the area called "Water London." This body is to consist of representatives of the City of London, the Metropolitan boroughs, the borough of West Ham, the district councils of East Ham, Leyton, and Walthamstow, the county councils of London, Kent, Middlesex, Surrey, and Hertfordshire, and the Conservancies of the Thames and the Lee. The present undertakings of the metropolitan water companies are to be acquired either by agreement or by purchase, and payment for these properties is to be made in water-stock which is to yield a fixed interest of 3 per cent. The purchase price is to be settled by a specially appointed court of arbitration consisting of the Right Hon. Sir EDWARD FRY, formerly a Lord Justice of Appeal; Sir HUGH OWEN, G.C.B., late Permanent Secretary to the Local Government Board; and Sir JOHN WOLFE BARRY, K C B, the well-known engineer. The terms of the arbitration are to be unfettered, except that the arbitrators are not to allow anything for compulsory purchase—a point insisted upon by Lord LLANDAFF who declined to entertain the idea suggested by counsel that a shareholder in a water company could take a "sentimental interest" in a filter-bed. Such are the main lines on which the Bill is founded. It is to be regretted that in the course of his speech Mr. LONG made an inexplicable statement in regard to the London County Council which was calculated to cause annoyance to the majority of that body and could not conceivably be of service to anyone. Mr. LONG said that "if the Council felt aggrieved because they had not by this time become the water authority they must blame themselves rather than the Government or Parliament." This statement, puzzling to those who hold that the London County Council has no just claim to jurisdiction over "Water London," could not fail to be irritating to admirers of the proceedings of the London County Council, and it may have caused Sir H. CAMPBELL-BANNERMAN to give vent to some of the banalities with which he continued the debate.

No time need be spent in the contemplation of any arguments for or against the Bill which have their origin in party strife. We desire now to recall briefly the measures which have been recommended by THE LANCET for the final and satisfactory settlement of the London water question. The necessity which exists for an ample supply of good water is not obviated by the differences which exist among contending political factions as to what body or bodies would best manage the undertakings of the water companies, a fortuitous concourse of trading associations which at present give an intermittent and often unsatisfactory supply. We must insist once more on the fact that an ideal supply of water for London would ensure that the quality of the water should be pure and derived from sources beyond the suspicion of pollution, and that the quantity should be adequate, not only for domestic supplies, but sufficient to give an unstinted amount for municipal purposes. The public fountains should not be allowed to run dry, the ornamental waters of London and the canals should be clear and bright, a state of things which could only be made possible by frequent changes of the water, necessarily involving a supply greatly in excess of that which obtains to-day. It is of importance that the people of London should not be misled in this matter. It is obvious that a mere change of ownership of the existing sources will neither increase the quantity of water nor ensure its purity. At the present time the metropolitan water companies are legally, and should be in deed and in truth, controlled in many essential matters by the Local Government Board. We have frequently found it necessary to refer to the neglect displayed by the Board in carrying out its duties in this respect; and we have urged on the Government the duty which was imposed on it to obtain for the Board the additional powers of control which the BALFOUR and LLANDAFF Commissions advised were necessary for the protection of the people of London. If these powers had been obtained, as advised by these successive Royal Commissions and as we have persistently advocated, a large amount of information at present withheld by the water companies would have been in the possession of the Local Government Board.

It must not be taken for granted that purchase on behalf of the people of London of the metropolitan water companies' undertakings would be advantageous to the people. It cannot be said that the speech in which Mr. LONG introduced the measure brought forward any serious argument in favour of that hypothesis. Should the Bill pass it will

An allowance of £12 will be paid to every medical officer on first appointment for the purchase of camp outfit, particulars of which are given. The ordinary tour of residential service is one year, followed by leave with full pay during the voyages to and from England, and for four or two months clear in England, according as the officer *is returning for further service in West Africa or not.* Every medical officer, unless specially exempted, is engaged in the first instance on probation for one year, and if he is found not qualified for efficient service his appointment may be cancelled at any time within the year. Private practice is allowed under certain conditions. Free furnished single quarters are provided at all the recognised stations; further information on this point may be obtained at the Colonial Office. On attaining the age of 50 years, or after 18 years' service, an officer is qualified for a pension, or in the alternative he may retire at the end of nine years with a gratuity. Applicants for appointment must be of European parentage, and be between 25 and 35 years of age, and must possess a complete double qualification. Preference will be given to unmarried candidates. They should, in the first instance, apply in writing to the Assistant Private Secretary to the Secretary of State, Colonial Office, Downing-street, London, S.W., stating their qualifications generally and inclosing a certificate of birth. A form of application will then be forwarded to them to fill up and to return together with testimonials. Candidates selected for appointment will be required to attend either the London or the Liverpool School of Tropical Medicine, the cost of the tuition, fees, board, and residence, being borne by the Government.

## VACCINATION AND SMALL-POX.

THE Registrar-General's return for the week ending Jan. 25th contains a table and explanatory remarks, which appear to us so important at the present time as to deserve insertion in our columns. We cannot doubt that this information will be welcomed by those amongst the anti-vaccinationists (if there be any) who still desire to know the truth in such matters. In the following table the deaths from small-pox which have been registered from the beginning of the present epidemic down to Jan. 11th, 1902, are classified in minuter detail as regards vaccination than was possible at the date of issue of the several weekly returns:—

| — | All ages. | Ages at death. Under one year | 1-5 | 5-10. | 10-15. | 15-20. | 20-40. | 40-60. | 60 and upwards. |
|---|---|---|---|---|---|---|---|---|---|
| Vaccinated in infancy only ... ... ... ... | 130 | — | — | — | 1 | 3 | 76 | 45 | 5 |
| Revaccinated *more* than 10 years ago ... | 3 | — | — | — | — | — | 1 | 1 | 1 |
| Revaccinated *less* than 10 years ago .. | — | — | — | — | — | — | — | — | — |
| Vaccinated, only after infection by small-pox ... ... ... ... | 14 | 7 | 2 | — | — | 1 | 4 | — | — |
| Unvaccinated ... ... | 116 | 10 | 35 | 14 | 16 | 15 | 19 | 6 | 1 |
| No evidence of vaccination ... ... ... | 9 | — | — | — | 1 | — | 5 | 3 | — |
| Stated to have been vaccinated; scars, if any, obscured ... | 28 | — | — | 3 | 1 | — | 12 | 10 | 2 |
| Total ... ... ... | 300 | 17 | 37 | 17 | 19 | 19 | 117 | 65 | 9 |

The table shows that out of those children and young person under 20 years in the population of London who were not protected by vaccination, 100 have recently died from small-pox; whilst only four deaths from that disease have occurred among those of the same ages who were ascertained to have been vaccinated in infancy. There are also five cases in which the evidence was insufficient to warrant a definite statement as to vaccination. If the extreme course be taken of counting these five cases with the *vaccinated, the figures will show at least 100 deaths from* small-pox among the unvaccinated section of the population under 20 years of age, and at most nine deaths among the vaccinated section at the same ages. At ages over 20 years there were 30 deaths of persons who were admittedly unvaccinated, 126 of persons who had been vaccinated in infancy but not revaccinated, and three of persons who had been revaccinated. In all these three cases revaccination had taken place more than 10 years ago, and in two of them it is uncertain whether the operation was successful. There are also 32 cases at these ages in which the facts as to vaccination could not be definitely ascertained. In 24 of these cases statements were made to the effect that the deceased had been vaccinated, but in none of them was it claimed that the deceased had been revaccinated. Medical practitioners would greatly facilitate the classification of deaths from small-pox in the Registrar-General's office, if they would add to their certificates (*a*) the duration of the disease (i.e., the time between attack and death), and (*b*) the date of vaccination when this is known.

## LABELS AND LIABILITIES.

IN our issue of Jan. 4th, p. 44, we referred, in regard to a recent regulation of the General Medical Council, to Section 17 of the Pharmacy Act of 1868 and expressed the opinion that according to this section medical men who dispensed their own medicines containing scheduled poisons were, if they obeyed the strict letter of the law, compelled to label whatever vessels contained the medicines in question with their names and addresses. If this reading of the Act is correct, as we believe it to be, a new difficulty arises for medical men dispensing scheduled poisons. As a correspondent points out (his letter will be found in another column) the practitioner seems to be torn between the appearance of self-advertisement and a breach of the law. This arises from the condition before referred to which, according to the Pharmacy Act of 1868, applies alike to medical practitioners and to persons registered under that Act. Although the former are specially exempted from certain conditions imposed upon the latter as regards medicine containing a scheduled poison, yet this provision includes them too—viz., "that such medicine be distinctly labeled with the name and address of the seller and the ingredients thereof be entered with name of person to whom sold or delivered in a book to be kept by the seller for that purpose." The second part of this provision is answered by the practice, universal we imagine with even the most busy or more careless of practitioners, of entering prescriptions in a book against the name of the patient for whom the medicine was prescribed. Such a practice is obviously necessary even from the merely business point of view to facilitate the accurate making up of accounts. It is the first part of the condition, however, which has so perturbed our correspondent, and we cordially sympathise with his consternation. It seems to him to savour of advertisement and, in a way, to level the position of the medical man who dispenses his own medicine to that of the druggist in his shop for the practitioner thus to label with his name and address the bottles or boxes in which medicines are sent or given out that happen to contain as ingredients one or more of the scheduled poisons. If the law did not happen to require such a step would it not be exactly the kind of thing to which the General Medical Council, sensitive of the dignity and propriety of indifference of the more highly educated graduates in medicine—he quotes from a letter received by him from an able and experienced army medical officer. As a rule, army medical officers, from scruples which if at times inconvenient or even fastidious are nevertheless to be honoured, regard themselves as precluded from public controversy in such matters even after their retirement from the army. We may therefore attach some importance to such expressions of opinion when we get them.

Professor ALLBUTT'S correspondent shows that he is animated by a proper appreciation of science, and he knows how to express his views vigorously. In regard to the proposed multiplicity of examinations he strongly supports the objections entertained by Professor ALLBUTT, and, we may add, by almost everybody else who has given any thought to Mr. BRODRICK'S scheme in the form in which it was originally published; and he calls attention to the writing up of case-books without any regard to the interest of the cases recorded as one of the bugbears of station hospital life, at the same time pointing out how these case-books could be greatly turned to account, if properly used, in forming an estimate of a medical officer's ability, merits, and fitness for promotion. The fact must, we think, be admitted that there has hitherto been little or no encouragement in the service for the cultivation of a scientific spirit or for the exhibition of professional merit. Professional skill and zeal led nowhere and brought no success or satisfaction beyond that which belongs to a sense of duty conscientiously done. It has been through military rather than medical channels that rewards have come to the Army Medical Service. We have often lamented that this should be so, as our readers know, and have expressed keen hopes of seeing it altered, and medical officers relieved, as far as practicable, of many irksome clerical duties so that they may have more leisure for important study. Professor ALLBUTT'S correspondent also alludes to the supply of medical and surgical appliances and instruments for the Army Medical Service. It is needless to say that all that is required for the sick and wounded in our army should be available and should be of the best patterns. But it has to be recognised that the supply of instruments and remedies, and their preservation in a good state under all the conditions affecting the army at home and abroad, must be often attended with financial and administrative difficulties, especially considering how the tendency is for such stores to become obsolete.

Two other points in Professor ALLBUTT'S letter call for comment. He writes:—

> "However welcome an increase of pay may be to all of us, whatsoever our callings in life, such increase is not a cardinal factor in the reformation of the Army Medical Service. As in the combatant ranks, so in the scientific, there are many able men who would find compensatory attractions in the service. ...... The medical officer, as such, lies under no social disadvantage; on home and foreign stations alike, a well-bred and pleasantly-tempered man finds himself received on terms of intimacy and equality in all military and social circles."

These are the views alike of Professor ALLBUTT and of his correspondent. Whilst concurring generally in them we cannot shut our eyes to a matter which medical officers may consider it undignified to notice, but which should not be altogether ignored—namely, the reprehensibly exclusive action of some of the service clubs in regard to the medical officers of the army. Young men of good social standing and training will not join a service in which their brother officers refuse them social equality. As long as the army medical officers find it difficult to secure election to the service clubs, simply because of the branch of the service to which they belong, so long will a certain section of young medical men hold aloof from that branch. Nor do we think that the question of pay can be left quite so much in the background as Professor ALLBUTT would leave it. Many letters in our columns have shown that the question is a very prominent one in the minds of the officers of the service.

Dr. C. B. BALL, a member of the new Advisory Board, has recently delivered an address to the Dublin Branch of the British Medical Association, on the Re-organisation of the Army Medical Service, in which he recognised that the pecuniary considerations must not be neglected. His assurance that no intention existed to deprive medical officers of their right to retire under existing regulations on £1 a day after 20 years' service is satisfactory. Although we never quite believed that such an intention really existed, it must be confessed that the wording of the report of Mr. BRODRICK'S Committee in this respect was vague. In some other matters—as regards the questions of examinations and of increased pay to medical officers whilst serving in India for example—Dr. BALL expressed his belief that certain changes would be made and a satisfactory settlement would be arrived at. He likewise gave some interesting details relating to the proposed establishment of a large military hospital in London with a staff college attached. This he regarded as a very important step and one which, he said, to his surprise, had attracted but little notice. He will find, however, that this was a point specially dwelt upon in the series of articles upon the Army Medical Service which appeared in THE LANCET during the past year.

# Annotations.

"Ne quid nimis."

## THE WEST AFRICAN MEDICAL STAFF.

THE Colonial Office has announced that the medical services of the West African colonies and protectorates —viz., the Gambia, Sierra Leone, the Gold Coast, Lagos, Southern Nigeria, and Northern Nigeria—will in future form one service under the name of the West African Medical Staff. All the medical officers will be selected by the Secretary of State for the Colonies, and will be on one list of employment and promotion. The grades and salaries are as follows: principal medical officer, with a minimum salary of £1000, rising by annual increments of £50 to a maximum of £1200; deputy principal medical officer, with a salary of £700, rising by annual increments of £25 to £800; senior medical officers, with salaries of £600, rising by annual increments of £20 to £700; and medical officers, with salaries of £400, rising by annual increments of £20 to £500. For Sierra Leone and Lagos the principal medical officer has £800 per annum, rising to £1000. Various extra allowances are made under the head of horse or hammock allowance, out-of-pocket travelling expenses, field or bush allowance, and allowances on military expeditions.

cough, the commoner nervous lesions being convulsions or paralyses. The development of paralyses is due to a "cerebral lesion of an inflammatory or mechanical character," resulting from the whooping cough. 2. The following table gives a *résumé* of the nervous accidents which may result:—

- 1. Psychoses
  - *a* Delirium, hallucinations.
  - *b* Depression of spirits (apathy).
  - *c* Imbecility.
- 2. Neuroses
  - *a* Hysterical attacks.
  - *b* Epileptiform attacks.
  - *c* Choreiform and other convulsive attacks.
- 3. Motor Troubles
  - *a* Convulsive—e.g., eclampsia, cramps, and spasm of the glottis.
  - *b* Paralytic—e.g., hemiplegia, monoplegia, and aphasia.
- 4. Sensory Troubles
  - *a* Anæsthesia.
  - *b* Deafness.
  - *c* Blindness.
- 5. Rare forms of sclerosis—e.g., bulbar and disseminated sclerosis and possibly Friedreich's disease.

3. The total number of cases of paralyses in whooping cough investigated was 83. Of these 25 were recorded prior to 1880, 18 were recorded during the period 1880 to 1890, 10 during the period 1890 to 1895, and 30 during the period 1895 to 1901. Most of the cases included in the last group were studied personally and from his observations Dr. Valentin concludes that such paralyses must be more frequent than is commonly supposed since during six years 30 cases were observed. 4. In 62 cases the ages are mentioned, 58 being children of from one to 12 years of age. The largest proportion of paralyses was met with during the ages from two to six years inclusive. 5. The proportion of paralyses in boys was one half of that of girls and as whooping cough in general affects children in the proportion of four boys to five girls (as shown by the extensive statistical tables of Dr. West), it is concluded that the female child has a greater proclivity to paralysis from whooping cough than has the male. 6. The cerebral paralyses observed were distributed as follows: 16 were examples of monoplegia (of the arm and less frequently of the face) or loss of speech or sight; 40 were cases of hemiplegia (right sided in 21, left sided in 15, and not stated in four), while paraplegia was rarer and affected only five or six cases. Right-sided hemiplegia was often accompanied by aphasia. 7. Paralyses from ponto-bulbar or spinal lesions were distinctly rare, only two cases of each class having been met with. 8. Necropsies conducted in several cases showed that the nervous lesions underlying the paralyses were hæmorrhage and softening and that occasionally minute hæmorrhages gave rise to small foci of sclerosis. 9. The prognosis in the case of paralyses from whooping cough was very grave. Of 64 cases specially investigated in this connexion it was found that 14 patients died, 22 remained permanently paralysed and enfeebled, and the rest (two-fifths of the whole number) recovered almost completely.

## THE CAUSATION OF EPILEPSY.

AN interesting discussion at the New York Academy of Medicine on the Causation of Epilepsy recorded in the *Medical News* of Jan. 11th was opened by Dr. Louise Robinovitch, who based her observations on a large number of cases studied at the Asile St. Anne, Paris, under Professor Magnan during the last few years. From these observations it appeared that in the majority of cases a history of alcoholism could be obtained in the parents of the epileptics. Epilepsy in this respect seemed to be associated collaterally with insanity. Thus of 140 patients whose histories were carefully followed up 90 proved to be descendants of alcoholic parents—a proportion of 64 per cent. In addition to this must be noted the proclivity to infantile convulsions in the offspring of alcoholic parents. Dr. W. C. Hollopeter of Philadelphia cited the case of a professional friend whose brothers were epileptic, this condition being probably the result of parental alcoholic intemperance. Dr. Bell of New Jersey stated that he had under his care a family of seven children, most of whom suffered from some form of nervous disorder resulting from the hereditary taint transmitted by the father who was a confirmed dipsomaniac. In another case known to him of a family of six children, five of whom were neurotic, ancestral alcoholism was held to be the predisposing cause. He, however, cited the case of a young woman who had epileptic attacks regularly before and after her catamenia, probably as the result of malarial infection, alcoholism as a cause being positively excluded in this instance. Dr. Berg contended that many working men who took from six to eight glasses of beer a day (the equivalent of two litres of *vin ordinaire* in France) could not be designated as alcoholics. Dr. Robinovitch, in reply, stated that two litres of wine were regarded as excessive in France by the highest medical authorities and that such an amount of alcohol was more prejudicial to the excitable Frenchman than to the phlegmatic German, and that it predisposed to epilepsy.

## SMALL-POX IN LONDON.

THE number of cases of small-pox in London continues to increase. Thus on Friday, Jan. 31st, there were 93 fresh cases notified and removed; on Saturday, Feb. 1st, there were 75 fresh cases; on Sunday, Feb. 2nd, there were 42 fresh cases; on Monday, Feb. 3rd, there were 75 fresh cases; on Tuesday, Feb. 4th, there were 32 fresh cases; and on Wednesday, Feb. 5th, there were 37 fresh cases. No medical man wants to be told that vaccination and revaccination are the sheet-anchors in the struggle against small-pox, but it is often difficult to persuade persons who ought to be vaccinated or revaccinated to undergo the operation. The reasons for this are various. In the case of a very few persons it is due to sheer pigheaded obstinacy, in many to ignorance, and in many more to a fear that they will lose a day's work or even more owing to being laid up. In reference to this point the Rev. S. A. Barnett writes from Toynbee Hall to the *Times* of Feb. 4th as follows:—

> A firm employing a large number of people in this neighbourhood gave notice that a doctor would attend at the works and that no one should lose wages on account of loss of time consequent on the operation. The people in response to this notice willingly offered themselves, even the anti-vaccinators." Perhaps, Sir, other firms and employers learning through your columns of such public-spirited action may themselves do likewise and so the plague may be stayed.

We warmly congratulate the firm in question upon their action, and can only echo Canon Barnett's plea that other firms and employers should go and do likewise.

## THE COMING OF THE SANITARY ENGINEER.

THE address to the Institute of Sanitary Engineers at the opening meeting of the session of 1902, which was held recently, was given by Dr. J. C. Thresh, the President of the Institute. He pointed out that sanitary engineers existed more than 2000 years ago and that the remains of the sanitary works of ancient Rome still excited our wonder and admiration. But when the Roman empire and Rome itself were destroyed by the barbarian invasions aqueducts were thrown down and the escaping waters flowed over the plain and forming marshes greatly contributed to the spread of malaria, while the sewers were choked up so that plagues and fevers had a fertile breeding ground. Mediæval cities with their crowded populations were in a filthy condition and even as late as the year 1842 the report of the Royal Commission appointed to examine into the sanitary condition of the labouring population revealed an appalling state of matters. In 1848 the first Public Health Act was passed and the sanitary engineer, after having been in abeyance for some 1500 years, again came into existence.

the profession, would make vigorous objection? As a matter of fact, such a practice is obviously distasteful to the general medical practitioner, for we imagine that this little piece of legal requirement will be news to many, as the practice of it is certainly by most honoured far more in the breach than in the observance. We are unaware that either the General Medical Council or any legal body has ever found fault with a practitioner for thus ignoring a provision of the law and we very much doubt whether such a contingency will arise. To this extent, therefore, our correspondent's fears are ill-founded and we can only wish him, and doubtless hundreds of his fellows, a continued immunity from interference for neglecting a legal requirement the observation of which appears derogatory to their professional dignity. The subject of the sale of poisons is, however, now under the consideration of a Parliamentary committee.

## THE POLICE OF LONDON IN 1900.

THE report annually issued by the Chief Commissioner of Police of the Metropolis, like some other works of the same kind, loses a little of its interest owing to the length of time apparently necessary for its compilation. At the beginning of 1902 we feel an indifference towards the statistics of 1900 that we should not feel towards those of 1901. If, for example, the tables that Sir Edward Bradford now submits to us showed a sudden increase of a particular form of crime, or an unwonted mortality in the police force from some unusual cause, we should feel that, as far as extraneous influence or criticism was concerned, the opportunity was over. The present report, however, does not show anything abnormal, although it contains much that is of interest. Turning to the section of it which is signed by Mr. A. O. Mackellar, chief surgeon of the metropolitan police, we find the average daily diminution of this little army of about 15,800 men from sickness to have been 3·33 per cent. The different form adopted in the reports of the county and borough police forces does not enable us to make a general comparison as to this, but if we turn to the statistics of the county and borough police forces for the year ending Sept. 29th, 1900, and observe the Liverpool figures for example, we see that the conditions of London life render the lot of a Metropolitan constable a happier one than that of his comrade in the north. During the three days in which the Liverpool police were inspected over 5 per cent. were absent through being on the sick-list, while there were 1363 convictions in 1899 for assaults committed on the Liverpool police, a body of 1460 men, as compared with 2807 convictions for assaults in 1900 upon the London force, which has an authorised strength of 15,847. Assaults are, of course, not the only causes of the injuries which put a policeman on the sick-list. Mr. Mackellar divides these injuries into two classes—those received in the execution of duty and those received from accidental causes whilst on duty. In the former class 2867 men, when making arrests, were assaulted or injured by prisoners and other persons, 77 were injured when stopping runaway horses, and 53 were bitten by dogs and seven by horses. As instances of the second class may be mentioned 291 cases of injury by slipping in the streets or when examining premises, while 101 cases arose from accidents connected with horses. The liability of the police to suffer from disease may best be gauged by the tables of deaths and of the causes of retirement through being invalided. Pneumonia accounts for 20 out of a total of 86 deaths, but two of these cases appear to have been among army reservists serving in Africa. Cardiac disease caused death in six instances. Disease of lungs accounts for 15 cases of retirement, "rheumatism, rheumatic gout, and sciatica" for 12, neurasthenia for eight, cardiac disease for eight, and varicose veins for seven, the total number of retirements also being 86. In another table we find the number of men placed on the sick-list owing to diseases due to exposure in the first half of the year compared with those similarly affected in the second half.

*Table of the Chief Diseases of Exposure in 1900.*

| Disease. | Half-year ending June. | Half-year ending December. |
|---|---|---|
| Rheumatism, "chronic and muscular" ... .. . | 521 | 451 |
| Catarrh . .. . . . . . | 1490 | 626 |
| Bronchitis . . | 184 | 62 |
| Tonsillitis .. ... | 250 | 221 |
| Totals ... . . ... | 2445 | 1360 |

Of the sick and injured of the police there were admitted to general hospitals on the recommendation of the chief surgeon or divisional surgeons, and with the consent of the Commissioner, 202, and to cottage hospitals 100. Evidence of the high moral standard maintained in the metropolitan police is to be found in the fact that in this large force of men in the prime of life there were only 18 cases during the year of suspension from duty owing to venereal disease. Passing from vital statistics to other matters, the figures relating to the licensing of public vehicles are of some medical interest. Many Londoners as they pass middle age are inclined to regret the preponderance of hansom cabs over the steadier and less draughty variety with four wheels, particularly in cold and wet weather, and are also obliged frequently to find fault with the odoriferous and insanitary qualities of the "four-wheeler." The numerical preponderance of the hansom cab is not so great in fact as it is apparently, but no doubt a large number of "four-wheelers" are exclusively employed at railway-stations. In 1900 there were 7,531 two-wheeled hackney carriages licensed and 3721 four-wheeled, being an increase of 87 four-wheeled and a decrease of 28 two-wheeled vehicles. By the way, we note that the official name for a four-wheeled cab is a "clarence," a title originally given to vehicles of the brougham class out of compliment to the Duke of Clarence, afterwards William IV. In perusing this portion of the Commissioner's report we might speculate on the cerebral conditions which cause 3239 persons to leave their purses and 180 persons to leave their watches in public carriages; the other articles, such as rugs and umbrellas, found by drivers and conductors and deposited with the police being more suggestive of temporary forgetfulness. We regret to observe that although the convictions for furious driving appear to have a tendency to diminish, the convictions for drunkenness among cab-drivers and omnibus-men were higher in 1900 than in the preceding year. The increase, however, is not important, and, as we have said, we feel inclined to regard 1900 with an indifference that we should not accord to 1901.

## PARALYSES IN WHOOPING-COUGH.

DR. PAUL VALENTIN of Paris in a recent *Thèse de Paris* (1901) refers to the little-known subject of paralyses in whooping-cough, a matter of practical importance especially in regard to prognosis. The occasional occurrence of paralysis after whooping-cough was noticed in the eighteenth century by Sydenham, who noticed the fact that infants affected with it may have difficulty in walking. Dr. Valentin has collected from medical literature a total of 83 observations on paralyses in whooping-cough, including a number of personal observations, and summarises his results as follows. 1. Psychoses and neuroses are rare accidents of whooping-of plague was threatened. It is evident, however, that no trustworthy method has yet been discovered. From the partial success obtained by Dr. Abel, however, it may be hoped that further investigations will be made and also that the statement will be corroborated that the Danysz bacillus is harmless to man and to domestic animals.

## POPULAR LECTURES ON HEALTH QUESTIONS.

SANITARY science is of comparatively modern creation, and the slowness with which its teachings are accepted in some quarters makes it all the more desirable that every means should be used to arouse general interest in measures which have for their object the preservation of health. Popular lectures may do good service in this respect, provided that the lecturers are themselves well informed and possess the valuable faculty of imparting their knowledge in an easy and untechnical manner. In a lecture on Matters connected with the Life and Health of the Public, delivered at Southend by Dr. J. T. C Nash, the medical officer of health, both these conditions have been realised, and the Health Committee of that town has acted in the public interest by having a summary of it printed and extracts made for distribution. Dr. Nash showed that free ventilation, efficient disinfection, and general cleanliness, municipal and personal, were synonymous with the destruction of pathogenic bacteria, and conversely that municipal and personal uncleanliness were the principal factors in the production of disease. Under the heading of small-pox he explained in simple but impressive phraseology that efficient vaccination was the only protective against the infection, but that after the lapse of some years the immunity gradually became less and revaccination was required.

## CHOLERA AND FAMINE IN BENGAL.

IN a paper entitled "Bengal—the Land and its People," read before the Society of Arts on Jan. 23rd, Mr. Francis Henry Skrine made some interesting remarks on the origin of cholera and famine in our Eastern dependency. Mr. Skrine, although not a medical man, has had a large Indian experience, and in 1891, whilst magistrate-collector of Rungpore, he was more than once officially thanked by the lieutenant-governor of the province for the work done by him in connexion with an outbreak of cholera. The disease, he says, is indigenous to Bengal, but there is reason to suppose that its appearance in an epidemic form is of comparatively modern date. The Mughal sovereigns used to spend the greater part of each year in perambulating their empire, attended by hundreds of thousands of followers, but these progresses would be impossible at the present day, for a "camp" on anything like the old scale would speedily be dispersed by cholera. Some soldiers disbanded after the European peace obtained grants of waste land in 1816 in the Sundarban, an alluvial tract on the fringe of the Bay of Bengal, and in clearing the ground and bringing the soil under cultivation they seem to have let loose the cholera germ. In 1817 Jessor, the district to which the Sundarban at that time belonged, was desolated by cholera. The disease then spread to Calcutta, caused many deaths in Lord Hastings's army opposed to the Pindaris, and travelled to Eastern Europe by the caravan routes, striking Paris and London in 1831. In Indian towns with a pure water-supply cholera appears only in a sporadic form; in country districts it is connected with the tax on salt, for salt is so dear that it is seldom given to cattle which satisfy their craving by devouring excrementitious matter, and in this way Mr. Skrine believes milk is infected with the cholera germ. In the causation of famine the most important factor is an ill-distributed and improvident peasant proletariat and the next is the deterioration in the productive power of the soil. The staff of life is rice, and if the crop fails, as it must do if the monsoons in July and October do not bring rain, there is nothing cheaper to fall back upon. An acre of land unreached by silt from the rivers now produces only 800 pounds of food grain, whereas in the days of Akbar the average yield was 1400 pounds.

## A PLEA FOR THE SEALED MILK-CAN.

THE milk supplied to towns necessarily travels some distance from the point of production before it reaches the consumer, and it is desirable that on its journey by road or rail precautions should be taken, not only to prevent its contamination, but its adulteration also. If milk can be watered *in transitu*, and there is no doubt that such adulteration often takes place on the way from the milk-shop to the house, the milk has necessarily also been exposed to the risk of contamination. The man with the barrow is not always above suspicion. There is no doubt that often good genuine milk is sent out of the shop and is afterwards mysteriously mixed with water before delivery. When large vendors are convicted of selling watered milk the defence is invariably raised that the milk was sold exactly as it was received from the farmer. Then when the farmer declares that he dispatched the milk just as it came from his cows, suspicion falls upon the railway servant or the inference is made that the tampering occurred on the railway. In both cases, therefore, of the tampering with milk, on the barrow and in the train, we possess a strong argument in favour of all milk, wholesale or retail, being supplied in sealed cans. It, however, has been stated pretty freely in court that the railway companies will not allow milk consignors to seal or to lock their cans, as it would interfere with the examination, the measuring, or the weighing of the contents. As a matter of fact this is not so, as has recently been shown by the medical officer of health of Islington, who has elicited a very definite answer upon the subject from the Railway Companies' Association. The reply was to the effect that "senders have been for a long time allowed to send milk in sealed cans, the companies accepting the declaration of the senders as to the quantity conveyed, no extra charge being made." The only condition which the companies require to be fulfilled is that the true weight of each can shall be stamped on the outside of the can, so that in case of doubt the quantity of milk within the can can be approximately ascertained by allowing 10¼ pounds for each gallon of milk declared. There is thus no difficulty in senders protecting themselves against alleged loss of milk *in transitu* by sealing, padlocking, or otherwise fastening the cans. It would be better still if the companies refused altogether to carry milk except in fastened cans—a step which, if adopted, would undoubtedly reduce the rate of milk adulteration and at the same time destroy the common and miserable defence of the large wholesale milk vendors that the farmer, the railway servant, in fact anybody but themselves was guilty.

## SMALL-POX AND ISOLATION.

ISOLATION hospitals are without doubt most useful institutions, but unless they are managed with a due regard to the risk of infection they become neither more nor less than centres of extreme danger. If we may judge from certain statements made at a meeting of the Barnet Rural District Council held on Jan. 23rd, the Clare Hall Small-pox Hospital at South Mimms seems to be managed in a manner which may mildly be stigmatised as careless. A letter was read from Mr. Sirey, landlord of the Guinea Inn at Ridge, wherein he contended that "this hospital or lodging-house for small-pox is not an isolation hospital at all" The writer also stated that the engineer and various members of the staff lived in the village, also that some of the patients, when well enough

Much still remained to be done, especially, concluded Dr. Thresh, with regard to the question of the housing of the working-classes. He pointed out that in many rural districts the local sanitary authorities had no control over the materials of which buildings were to be constructed and he suggested that the Institute should consider this subject with a view to improve the regulations of the Local Government Board. He might have added that in many instances the local builder is a member of the town council or sanitary authority with disastrous results. Not so very long ago our contemporary *Truth* pointed out a disgraceful state of matters existing at Reigate. Our sanitation has undoubtedly improved within the last 50 years, but the shoddy house built upon what is euphemistically termed "made ground" is still to be found. The penalties for insanitary or defective building or plumbing should be made really prohibitive.

## THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Mauritius, received at the Colonial Office on Jan 31st, states that for the week ending Jan. 30th there were 12 cases of bubonic plague, of which 9 proved fatal. As regards Egypt, during the week ending Jan. 26th 15 cases and 16 deaths have occurred from plague in Egypt: 14 cases and 14 deaths have been reported from Tantah, 1 case and 1 death from near Zifteh, and 1 death from Mit Ghamr. During the last week only 7 deaths have occurred out of hospital, in comparison with 13 during the week ending Jan. 19th. The disease at Tantah is confined chiefly to the Soudanese population, and this accounts for the heavy hospital mortality, as these people succumb to the disease much more readily than do the Fellaheen.

## EXAMINATION OF THE BLOOD FOR THE TYPHOID BACILLUS AS A MEANS OF EARLY DIAGNOSIS OF TYPHOID FEVER.

TYPHOID bacilli have been found by a number of observers to be present in the blood with great frequency—in from 70 to 80 per cent. of their cases. At the meeting of the Société Médicale des Hôpitaux of Paris on Dec. 27th, 1901, M. Jules Courmont pointed out the great value of this fact in the early diagnosis of typhoid fever, especially when Widal's reaction failed. He examined the blood in nine cases and succeeded in obtaining the bacillus in pure culture in all. The blood was taken aseptically at the bend of the elbow and was cultivated in small flasks containing 20 cubic centimetres, and in larger ones containing from 300 to 1000 cubic centimetres, of bouillon. Into the smaller ones some drops of blood were received and into the larger ones from two to four cubic centimetres. Incubation took place at 37° C The bacilli obtained showed all the typical characters of typhoid bacilli. M. Courmont drew the following very important conclusions. 1. The typhoid bacillus was present in the blood in all ordinary and grave forms of typhoid fever (the question of slight and abortive forms he reserved). 2. It appeared early in the disease. He found it as early as the fifth day (he had not an opportunity of examining the blood earlier) It remained in the blood until the end of the third week It might persist longer in fatal or prolonged cases At necropsies it might be found in the general circulation. The best method of obtaining cultures was to cultivate from two to four cubic centimetres of blood immediately after it was taken in from 300 to 500 cubic centimetres of bouillon. If the bouillon was not turbid at the end of 24 hours the deposit should be shaken up. With the small quantities of bouillon M. Courmont [illegible] successful in only 21 per cent. of the cases. The agglutinability of the bacilli was usually inferior to that of those employed in Widal's test; it increased in the successive generations in bouillon until it became equal to that of Widal's test. There was no relation between the presence of the typhoid bacillus in the blood and the agglutinating power of the serum. The bacillus was found in the blood in four cases at an earlier period than that at which the Widal reaction could be obtained. In two it was found on the fifth and ninth days respectively, while Widal's reaction was not obtained until the twenty-second and forty-fifth days. These observations show the great diagnostic value of examination of the blood for the typhoid bacillus, especially when Widal's test is negative.

## THE NEW MEDICAL OFFICER TO THE LONDON SCHOOL BOARD.

DR. JAMES KERR of Bradford has been elected to the post of medical officer to the London School Board. Dr. Kerr, who has acted as medical superintendent of the Bradford School Board, was educated at Cambridge and St. Bartholomew's Hospital, graduating as M.D. in 1891. He is well acquainted with the various subjects bearing on school hygiene and has written much on the subject. Dr. Kerr will receive a salary, to commence with, of £800 per annum, which will eventually rise to £1000. We are glad to see that he is to give his whole time to the service of the Board.

## DANYSZ'S VIRUS AS A DESTROYER OF RATS.

SOME years ago Dr. Danysz of Paris discovered a bacillus which has been called the bacillus typhi murium (Danysz). It was shown to be pathogenic for rats, and its discoverer suggested that it might be employed instead of other poisons to kill these animals. It was further urged that the bacillus was harmless to man and domestic animals. Further investigations went to show, however, that when practically applied the proposed method was not satisfactory. In THE LANCET of August 17th, 1901, p. 440, we published a communication by Dr. Klein and Dr. Herbert Williams, entitled "Experiments with the Danysz Rat Bacillus." These observers showed that when rats were fed with cultures of the bacillus death only resulted in about 33 per cent. of the animals. But when a number of rats were fed on guinea-pigs which had died after inoculation with virulent culture the percentage of dead rats was certainly increased. When, however, similar experiments were tried in a warehouse the results were entirely negative. The observers also added a useful warning when they said that all laboratory experiments on rats kept in captivity must be conducted with care, since these animals are liable to succumb spontaneously. In THE LANCET of Sept 28th, 1901, p. 868, we drew attention to similar experiments conducted by Dr. M. J. Rosenau, assistant surgeon, United States Marine Hospital Service; his results showed that this virus was not likely to prove of any special value as a rat destroyer on a wholesale scale. In our Berlin letter of last week (Feb. 1st, p. 341), we published the results of investigations by Dr. Abel, a medical officer of the city of Hamburg. He found that by feeding rats on the livers and spleens of rats that had died after inoculations of the bacillus the toxic action could be continued through six generations. Attempts were then made to destroy rats in some localities where they happened to be abundant, pieces of bread treated with cultures of the bacilli being placed where the rats would be likely to find them. The results presented considerable variety, but were more successful than in the attempts which we have referred to above. If by means of the Danysz bacillus measures could be adopted by which rats could be destroyed the plan would be of considerable value where an epidemic but which will not necessarily be the area at present denominated "Water London." The Water Board is to be "a body corporate with a common seal" and will have power to acquire and to hold land. The Board is to consist of a chairman and vice-chairman and 67 members; the chairman and vice-chairman are to be appointed by the Board and will receive such salaries as the Board may determine. The constitution and proceedings of the Board are set forth at length in one of the schedules (Schedule 4, p. 24). They are necessarily of a complicated nature, and it would be useless to attempt to give a summary of them.

The arrangements for the transfer to the Water Board of the undertakings of the companies is provided for in the Bill in Clauses 2 to 8. Payment for the property of the companies is to be made in a newly created security to be called "water stock." On taking over the businesses of the companies the Board will exercise "all the rights, powers, and privileges of the companies" and will be subject to "all the duties, obligations, and liabilities" of the companies under all the Acts, "whether local or general," which at present affect them. After the issue of the water stock to the companies in payment for their properties the Chamberlain of the City of London will be under the obligation to deliver to the Water Board the stock at present held by him (under what are generally known as the sinking fund clauses of the companies' Acts). The stock so delivered will be cancelled and extinguished. Provisions are made for the exclusion of certain districts (now in Water London) from the government of the Board and for the supply in bulk of certain districts and persons.

Provisions for the redemption of the present debenture stock of the companies are made in Clauses 9 and 10.

The financial arrangements of the Board are dealt with in Clauses 11 to 17 inclusive. A "water fund" is to be established and all payments by the Board are to be made from that fund. Should there be a deficiency in the "water fund" any sum required to meet this is to be made good by the City of London and the parishes in the county of London and in the boroughs and urban districts outside London the councils of which are for the time being entitled to be represented on the Water Board in proportion to the rateable value appearing in the valuation lists. The amount of money so required is to be raised (1) in the case of the City from the consolidated rate; (2) in the case of a parish in a metropolitan borough from the general rate; and (3) in any other parish from the poor-rate.

Provisions are made for the Water Board as to the terms on which money may be borrowed, as to the issue of water stock (which is to bear interest at the rate of 3 per cent. per annum), and as to the way in which loans are to be discharged (the essential feature being that the water stock issued in payment for the companies' undertakings must be redeemed within a period of 80 years). The accounts of the Water Board are to be subject to public audit and ratepayers are to have the right to make objection to and, if they shall think fit, to appeal against them.

For the purpose of arbitration a special court is appointed. It consists of the Right Hon. Sir Edward Fry, Sir Hugh Owen, G.C.B., and Sir John Wolfe Barry, K.C.B. Provisions are made as to the rules to be observed by the arbitrators.

Clauses 19 to 28, which are grouped together as "Miscellaneous," deal with the subsidiary powers of the Water Board, the power of the Local Government Board to make provisional orders for certain purposes, provisions as to local inquiries, the publication by the Board of an annual report (which is to be laid before Parliament by the Local Government Board), and the "dissolution of water companies" (the New River Company alone is to survive, presumably as a land company, for it has great possessions). Provisions are made also as to "qualification of justices" (whose capacity to act will not be interfered with because they hold water stock) and local authorities are to be allowed to be heard against any Bill promoted by the Water Board (a privilege which should not be distasteful to the Parliamentary Bar).

Clauses 29–40 inclusive relate to "transitory provisions" for the maintenance of the undertakings of the water companies until (Clause 29) and after (Clause 30) the day appointed for their transfer to the Board. Clause 31 provides that anyone authorised by the Water Board "shall have free access to the works of any metropolitan water company for the purpose of inspecting those works." The remaining clauses deal with the payment of dividends to companies till the issue of water stock, with temporary advances (to meet the immediate necessities of the Water Board on its formation), with existing contracts and existing by-laws, with the treatment of the present officers and servants of the water companies, and with the compensation to be given to the auditor of the companies' accounts. There are transitory provisions as to the supply of water in bulk, and power is given to the Local Government Board to remove some minor difficulties which may arise. The last section of the Act provides that "all costs, charges, and expenses preliminary to and of and incidental to the preparing, applying for, obtaining, and passing of the Act incurred by the Local Government Board shall be repaid to that Board by the Water Board when established under this Act."

## "TACHIOL," A NEW ANTISEPTIC.

A NEW antiseptic, which seems likely to take a high place among those at present in use, was the subject of a communication made to the Royal Medical Academy of Rome on Jan. 26th by Professor Durante, to whose notice it was brought by Paternò, Professor of Pharmaceutical Chemistry in the University of Rome, who by experiments on bacterial cultures had already noted its great germicidal power. This new antiseptic agent is the fluoride of silver and has been christened "tachiol." Dr. Perez, one of Durante's assistants, is now engaged in making a complete investigation of its properties, a full account of which is promised shortly. Meanwhile the results already obtained are interesting and promising. The object aimed at in the inquiry has been threefold—namely, (1) to establish the germicidal effects of the preparation; (2) to ascertain its toxic power; and (3) to determine its possible therapeutic applications. In regard to its bactericidal properties, it appears certain that in solution of 1 in 150,000 it kills in the space of one minute the most resistant pyogenic organisms, such as the staphylococcus pyogenes aureus. A solution of 1 in 200,000 was found sufficient to kill in one minute the typhoid bacillus. With the spores of the anthrax bacillus the result varied, probably owing to the different degrees of resistance in these spores, but a solution of 1 in 1000 sufficed in from 20 to 30 minutes to kill completely spores obtained at a temperature of 18° C., which resisted steam for 15 minutes. In all cases, however, by contact with such a solution for the space of one minute, a large proportion of the spores lost their power of development. Compared, therefore, with other antiseptics, such as sublimate, and carbolic acid and its derivatives, tachiol takes a foremost place as a germicide, especially when in contact with albuminoid bodies under which condition sublimate loses much of its bactericidal power. The toxic power of tachiol, on the other hand, is much feebler than that of other antiseptics, a fact which constitutes one of the chief advantages of the new preparation. Injected into guinea-pigs and rabbits no ill-effects are observed until the quantity exceeds *one centigramme per 100 grammes of* the animal's weight. Larger doses are poisonous. As to the therapeutic uses of the antiseptic, this was tested on a large scale in different surgical affections either by disinfecting cavities or suppurating sinuses, or by endoarticular injection in tuberculous synovitis, or by treating various cases of endometritis, proctitis, and cystitis. Solutions varying in strength from 1 in 1000 to as much as 1 in 100 were employed for most of these; in cystitis and endometritis solutions of 1 in 5000 or 1 in 10,000 were used. In all cases the injection was well tolerated and no ill-effects were produced. The suppurative process was arrested in a relatively short time and an examination of the cultures made after the first application demonstrated an almost complete disappearance of the germs. Indolent ulcers were stimulated and the process of cicatrisation was hastened to a notable degree. In some cases of tuberculous disease with formation of fistulous sinuses gradual healing and complete obliteration occurred, in others associated with suppuration the discharge lost its purulent character and a remarkable improvement took place in the local conditions, although, up to the present time at least, the tuberculous foci have not been entirely destroyed. In cases of tuberculous synovitis with lesions of bone the results were not so marked, probably because the action of the salt is chiefly local and requires actual contact in order to be fully exercised. Absorption does, to walk in the grounds, had scaled the fence and had gone to the public-house. Female convalescents had been seen shaking hands with, and talking to, people over the fence. Councillor Clarke stated that the Local Government Board had been communicated with, but had replied that it had no authority to interfere. After some further discussion it was decided to send Mr. Sirey's letter to the Local Government Board, Councillor Clarke mentioning that there were 50 men working on the place at the present time. The other night he watched the gate and saw 29 men come out, 14 of whom were going to St. Albans. When asked if they were disinfected before leaving they replied "No." We can scarcely believe that such a monstrous state of matters as is implied in the above quoted statements really exists, but perhaps the South Mimms Small-pox Hospital authorities will kindly explain or deny the charges made. Our columns are open to them.

AT a meeting of the Medical Committee of the Hospital for Consumption and Diseases of the Chest, Brompton, held on Feb. 5th, it was unanimously resolved :—

> That the medical staff of the Brompton Hospital repudiate all responsibility for statements with reference to treatment of consumption by intravenous injection which have recently appeared in a daily journal The treatment in question is being tried by some members of the staff, but as yet no trustworthy results have been demonstrated.

THE Edinburgh University Club of London will hold its annual dinner at the Criterion Restaurant on Wednesday next, Feb. 12th, at 7.15 P.M., under the chairmanship of Dr. T. J. Maclagan.

PROFESSOR VON BERGMANN has been appointed a member of the German Privy Council.

# Pharmacological Notes.

### THE INJECTION OF OXYGENATED WATER IN THE TREATMENT OF INFANTILE DYSENTERY.

DR. ROCAZ,[1] in a contribution to the Société de Médecine et de Chirurgie de Bordeaux, recommends the injection of oxygenated water in the treatment of dysentery of children, especially where there is suppuration. Similar treatment has been employed previously by Blech in cases of the gastro-enteritis of children. Oxygenated water is scarcely toxic and is employed as a powerful antiseptic. Two or three injections are administered daily of oxygenated water ("10 volumes" in strength) diluted with five times its volume of warm sterilised water. Each of these injections is preceded by an evacuant injection. The quantity of liquid used depends on the age of the patient and still more on the toleration of the large intestine. In order to be efficacious the injection should be maintained as long as possible and should penetrate deeply. To this end it is well to employ a rather long but very supple tube, since the largest dysenteric lesions are situated on a level with the rectum. The patient should lie first on one side, then on the other, in order to bathe the whole of the colon with the liquid. Thus administered the injections are easily tolerated and cause no pain. Dr. Rocaz has treated 12 severe cases of dysentery by this method in children aged from two to 12 years ; all have improved rapidly after the first two or three days. The stools quickly change in appearance and contain less pus, and less blood, and are less frequent, the sphincter regains its function, tenesmus and abdominal pains disappear, fever, when present, subsides, the general condition improves, and in eight or 10 days the affection is completely relieved. It is necessary, however, to continue the treatment several days after apparent recovery until the stools become normal both in quantity and in quality, otherwise a relapse may ensue. Two cases are particularly mentioned. In the first a girl, aged eight years, was put under the treatment, though her recovery was not expected. vil-smelling pus, mixed with blood, was constantly escaping from the anus. In two days the odour was less fœtid and the patient gradually recovered. The other patient, a child three years old, was put under the treatment after having been affected with dysentery for more than a month. In addition to the usual symptoms fever and vomiting were in evidence, but they all disappeared in eight days.

### THE URINE OF NURSLINGS.

M. E. Lesné and M. P. Merklen[2] have examined the urine of healthy nurslings and of those suffering from gastro-enteritis. They point out that the urine of the latter resembles normal urine in colour, in density, and in quantity ; its composition approaches the normal, and there are other points of resemblance. When, however, the attack of gastro-enteritis is severe certain modifications are observed. Thus the quantity passed is less, as also is the quantity of urea, chlorides, and of certain other normal constituents, while certain salts may increase in quantity and pathological constituents—e.g., albumin and indican—may make their appearance; the urine also has a higher density.

### DYMAL : A NEW ANTISEPTIC POWDER.

This substance, dymal,[3] on account of its cheapness, provided that clinical reports continue to be favourable, should prove of service in cutaneous affections where large quantities of medicaments are required. Dymal is an odourless impalpable powder ; it may be used in the dry state or in the form of a 10 per cent. ointment, or as a local absorbent and antiseptic. It has been found useful for burns, ulcers, and running eczema ; in scaly eczema and in psoriasis its action is but little marked. In intertrigo dymal exercises a soothing and drying action. In ichthyosis an ointment with a wool-fat basis is recommended because of its prompt action on the itching surface. Ulcers of the leg and cutaneous gangrene lose their repulsive appearance and characteristic odour under the influence of this powder.

### THE VALUE OF LECITHINS AND NUCLEINS.

Dr. J. Laumonier[4] summarises at some length our present knowledge of the lecithins and nucleins. With regard to the lecithins he considers them to be stimulating to the general nutrition, principally on account of the phosphorus which they contain and by the action which they have on the nervous system. However, in their effect the isolated lecithins, of which the principal ingredient is glycerophosphoric acid, do not seem to be superior to the glycerophosphates or even to cod-liver oil. Considering that this oil contains organic bases and phosphates, besides possessing tonic and stimulating properties, it appears to be superior to the costly lecithin. But if lecithin be considered to occur in the yelk of egg, then it is necessary to study the nucleins which accompany it and assist its action. Dr. Laumonier discusses the discovery, constitution, sources, classification, and other points connected with the nucleins, and draws the conclusion that insufficient clinical observations have been made to warrant any definite statement regarding their value as remedial agents.

# THE LONDON WATER BILL.

THE Government measure introduced by Mr. Long is entitled, "A Bill for Establishing a Water Board to Manage the Supply of Water within London and Certain Adjoining Districts, for Transferring to the Water Board the Undertakings of the Metropolitan Water Companies, and for other Purposes connected therewith." The Bill was prepared and brought in by Mr. Long, Mr Ritchie, the Attorney-General, and Mr. Grant Lawson. It consists of 40 clauses and six schedules which occupy together 28 pages. The first clause deals with the establishment of the Water Board, its composition and chief duties. The Board is to be established for the purpose of acquiring by purchase and of managing and carrying on the undertakings of the metropolitan water companies, and to undertake the duties of supplying water within an area which will be defined, that the fee of five guineas should be increased to six guineas and should be paid on each occasion of admission to Parts I. and II. of the examination.

After some further formal business the PRESIDENT dissolved the Comitia.

# THE ARMY MEDICAL SCHOOL, NETLEY.

## DISTRIBUTION OF PRIZES.

IN the lecture hall of the Army Medical School, Netley, on Jan. 31st, the result of the examination lately held at the school was promulgated, and the prizes were distributed by Surgeon-General W. Taylor, C.B. (Director-General of the Army Medical Service), in the presence of Colonel W. J. Charlton (Principal Medical Officer at Netley), Lieutenant-Colonel G. Wilson, Colonel K. Macleod (Professor of Military Medicine), Colonel W. F. Stevenson, C.B. (Professor of Military Surgery), Dr. A. E. Wright (Professor of Pathology), Colonel H. Cayley, C.M.G., I.M.S., Lieutenant-Colonel W. E. Webb, Major W. Dick, and the military staff of the Royal Victoria Hospital.

Colonel MACLEOD read a report which stated that the work of the session had been most satisfactory. Out of the 27 surgeons-on-probation who had undergone the final examination 26 had proved themselves fitted to receive His Majesty's commission. 23 surgeons-on-probation of the Indian Medical Service had passed an examination in company and stretcher drill and had received certificates to that effect. They had given evidence of punctuality, diligence, and capacity in the pursuit of their studies, and their conduct while passing through the school had been excellent, and there had been a good tone throughout the school. The Herbert prize, consisting of about £20, given in memory of the late Right Hon. Sidney Herbert, who was President of the Royal Commission which resulted in the foundation of the Army Medical School, and which was awarded at the end of each course of instruction to the surgeon-on-probation who had evinced the highest proficiency in the special subjects taught at the Army Medical School, was awarded to T. S. B. Williams, I.M.S. The Martin gold medal, which was given to the surgeon-on-probation who took the highest place in military medicine and was intended to commemorate the late Sir Ranald Martin, was awarded to E. Bissett, I.M.S. The Professor of Medicine desired to call attention to the names of Surgeons-on-probation H. B. Steen, A. E. J. Lister, and A. W. Greig, all of the Indian Medical Service, as having particularly distinguished themselves throughout the examinations in military and tropical medicine. The Parkes memorial bronze medal, given to the surgeon-on-probation who took the highest place in hygiene, and which formed part of a memorial to commemorate the great services of the late Professor E. A. Parkes, had been won by A. E. J. Lister, I.M.S. The second prize in hygiene, a book presented by Mrs. De Chaumont in memory of her husband, the late Professor F. De Chaumont, F.R.S., was awarded to T. S. B. Williams, I.M.S., who gained the second place in this department of study. The Professor of Hygiene desired to make mention of Surgeon-on-probation R. J. Bradley, who had also particularly distinguished himself in military hygiene. The Montefiore prizes, two in number, which were founded by Mr. Nathaniel Montefiore, were awarded to Surgeons-on-probation E. A. Loch and A. W. Overbeck-Wright, both of the Indian Medical Service The first prize consisted of a medal with a cheque for £21, and the second of seven guineas. The Professor of Military Surgery desired that the names of the following gentlemen should be honourably mentioned in his department of study – J. E. Clements, R. E. Lloyd, and T. S. B. Williams, all of the Indian Medical Service. The prizes in pathology, which consisted of books and an oil immersion lens, presented on this occasion by Professor Wright, were awarded to Surgeons-on-probation T. S. B. Williams and A. W. Overbeck-Wright, both of the Indian Medical Service, while the name of A. W. Greig, I.M.S., was worthy of special mention as a pathologist. The prize-books for clinical and ward work, presented in memory of Surgeon-General Maclean, for many years professor of military medicine, were awarded to A. E. J. Lister, I.M.S. The prize for hospital administration, consisting of a bronze medal and £5, which had been established by Mrs. Marshall Webb in memory of her husband, the late Surgeon-Major-General W. M. Webb, who once held the office of Assistant Professor of Military Medicine in the school, had been awarded to S. H. L. Abbott, I.M.S. From a report issued by Lieutenant-Colonel W. E. Webb, it appeared that the results of the examination on this subject which had been held as a separate one for the first time, and to which all the surgeons-on-probation were subjected, had been on the whole very satisfactory.

Surgeon-General TAYLOR, having distributed the prizes, addressed the young officers who had been awarded His Majesty's commission, expressing the pleasure which it gave him to be present on such an interesting occasion, because the Royal Victoria Hospital at Netley was associated with many of his happiest days. He should like to take the opportunity of thanking Mrs. Webb for the prize which she had given in memory of her late husband, whom he remembered as a distinguished officer and gentleman, respected wherever he went. Speaking to those who had been students there recently he would remind them that they had hard work before them and their lives were in front of them. Perhaps before he proceeded further he might try to allay a little anxiety which existed in the minds of some of the officers of the school. There seemed to be an idea abroad that their death-warrant had been sounded, but that, he thought, only existed in the air. The man in the street knew it, but they did not know it at headquarters, and if there should be any change it would only be one of translation. Let them hope and believe that the translation would be for the improvement of the service so that it might soar to a higher sphere. Addressing the Indian medical officers he said he was in a position to do so, though he had not the honour to belong to their service, for he had served in the country in which they had chosen to spend their lives. It was a difficult thing to choose a career, but he congratulated them on their choice. The records of their service were far beyond dispute, and they had had in their service men who were historical and whose names would go down to posterity, not only as belonging to their profession, but as pioneers of civilisation who had done more for the welding together of their great Indian Empire than the men of almost any other service. It would be invidious to mention names, but they were all historical, and they could find them for themselves now that they were starting in their career. There was one great principle which he should like to impress upon them with all the power and force he could command, and it was that they had still a lot to learn from the time they first stepped on board the ship that was to take them out to India, and they should keep on learning until their last voyage home. They would find themselves in a land that was new to them, and there they would again have a lot to learn. They should store up knowledge for future use and should remember that to stand still was dangerous. He sometimes heard it said that both the Indian Medical Service and the Army Medical Service, to which he had the honour to belong, were not considered careers fit for men anxious to get on in their profession. That was all nonsense, absolute nonsense, because in the smallest station they could go to in India—it might be 500 miles from anywhere—they might obtain more surgical experience and practice than elsewhere, and it was not opportunities that would be wanted but capacity to take advantage of them. He urged them not to forget in their careers that they were professional men and that they should be kind, cheerful, and sympathetic with their patients. He wished them all a most successful career in the field to which they were going, and hoped that they would do well and come back to their own country to spend the later days of their lives with the full knowledge that they had done their duty with all their might.

Colonel CHARLTON also addressed those who had received commissions, trusting that they would never regret the day that they joined the Royal Army Medical Corps or the Indian Medical Service. He also expressed regret and sorrow at the loss they had sustained by the death of Surgeon-General R. Harvey, late Director General of the Indian Medical Service, who came there on the occasion of the last distribution of prizes. He had the privilege of serving under him and never met a kinder, more courteous, or abler medical man; he was thoroughly well-cultured and distinguished in his profession and just as successful as an administrator. They should all try to profit by the bright example of those who preceded them and to maintain at all times the honour of their service.

The company was afterwards entertained at luncheon by however, take place and the action extends to a certain, though as yet undetermined, distance through the tissues. But perhaps the most important application of tachiol in these experiments was made to determine its action in certain septicæmias, especially in anthrax septicæmia. The results were most remarkable. Of seven rabbits inoculated in the subcutaneous cellular tissue with virulent anthrax and either immediately after or within one, three, six, 12, 24, or 30 hours injected hypodermically with a solution of 10 centigrammes per 1000 grammes of weight, only those injected after 24 and 30 hours had any anthrax bacilli in their blood, and none of them showed any symptom beyond a local and transitory œdema. Three rabbits inoculated as controls with the same culture of anthrax died within 48 hours. It was also found that the substance could be safely injected into the veins, but in quantities not exceeding from four to five grammes at a time. More than this produced embolic phenomena, although by means of fractional injections of from one to three grammes extended over from three to four days as much as 10 centigrammes per 1000 grammes of animal could be thus introduced with impunity. Doubtless much experience of the new antiseptic will be required before it can be safely affirmed that it is an efficient remedy in septicæmia, but enough has been seen of its action to warrant the hope that in tachiol we possess a substance of an unirritating and but slightly toxic nature and of very high germicidal power.

## ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the Comitia was held on Jan. 30th, Sir WILLIAM SELBY CHURCH, Bart., the President, being in the chair.

The PRESIDENT announced that His Majesty the King had graciously consented to continue to be an honorary Fellow of the College

The SENIOR CENSOR (Dr. T. T. WHIPHAM) proposed, and the TREASURER (Sir DYCE DUCKWORTH) seconded, the following motion, which was unanimously carried and ordered to be forwarded to the proper quarter :—

> The President and Fellows of the Royal College of Physicians of London are deeply sensible of the great honour which the King has been pleased to confer on them by graciously consenting to remain an honorary Fellow of their body. They desire to assure His Majesty of their devoted loyalty to his Throne and Person and to beg His Majesty's acceptance of this expression of their gratitude and dutiful allegiance.

The PRESIDENT announced that he had appointed Dr. D. Ferrier Harveian Orator, and Dr. C. J. Cullingworth Bradshaw Lecturer for the year, and that the Council had appointed Dr. H. T. Bulstrode Milroy Lecturer for 1903.

The following gentlemen having passed the required examination were admitted Members of the College: Arthur Stanley Barnes, M.B., L.R.C.P. Lond. ; John Charlton Briscoe, M.B., L.R.C.P. Lond. ; Arthur Edmund Carver, M.B., B.A. Cantab., L.R.C.P. Lond. ; Otto Fritz Frankau Grunbaum, M.A., M.B. Cantab. ; Richard Crawshaw Holt, M.D. Durh. ; Charles Hunter, M.A., M.B. Aberd. ; William McCallin, M.D R U.I. ; Sheffield Henry Morier Neave, L R.C.P. Lond. ; and Charles Gabriel Seligmann, M.B., L.R C.P. Lond.

Licences to practise physic were granted to 118 gentlemen, and diplomas in public health (conjointly with the Royal College of Surgeons of England) to 26 gentlemen.

The College seal was set to a "Declaration of trust" settling the foundation of the FitzPatrick Endowed Lectureship.

The following communications were received :—

1. From the President of the proposed Egyptian Medical Congress of December, 1902, inviting the President of the College to accept the honorary presidency of the Congress.—The PRESIDENT stated that he had accepted the office.

2. From the Owens College, Manchester, inviting the Royal College of Physicians of London to send a representative to be the guest of the College at the celebration of the jubilee of its foundation, March 12th and 13th, 1902.—The PRESIDENT, at the request of the College, consented to represent the College.

3. From the Queen Victoria's Jubilee Institute for Nurses asking the College to appoint a representative on the Council. —Sir Dyce Duckworth was re-elected.

4. From Lady Priestley offering for the acceptance of the College a portrait of the late Sir William O. Priestley, M.D. Edin., F.R.C P. Lond.—The PRESIDENT, in accepting the gift, proposed that the grateful thanks of the College be accorded to Lady Priestley.—The motion was adopted.

5. From Mr. Thomas Wakley, jun., L.R.C.P. Lond., offering for the acceptance of the College two medals impressed with the head of Sir William Browne, a former President of the College (1765).—Dr. J. F. PAYNE explained the origin of the medals and proposed that the cordial thanks of the College be given to Mr. Wakley for the gift.—This was seconded by the TREASURER and was carried with acclamation.

6. From the Dean of the Medical Faculty, University of Edinburgh, reporting the award of the Charles Murchison scholarship in July last to Robert Veitch Clark, M.A. Edin.

7. From Mr. Cowell reporting the proceedings of the Council of the Royal College of Surgeons of England.

Dr. S. J. Gee, Sir R. Douglas Powell, Dr. F. H. Champneys, and Dr. S. J. Sharkey were elected councillors.

A report was received from the representative of the College in the General Medical Council on the proceedings of the Council affecting the College at the November session.

94, Gloucester-place, Portman-square, W., Jan. 20th, 1902.

DEAR DR. LIVEING,—I have to report for the information of the College that at the meeting of the General Council of Medical Education and Registration in November and December, 1901, it was resolved *on the motion of Dr. McVail*.—

"That a committee be appointed to prepare a report on the differences that exist between certain licensing bodies on the one hand, and the General Medical Council on the other, regarding the courses and conditions of study, and the recognition of the institutions and schools in which the required courses may be taken; and that the report be considered by the Medical Council at a special meeting when the Council will decide what action, if any, shall be taken, and in particular whether the circumstances are such as to require action to be taken under Section 20 of the Act of 1858."

I was nominated to serve on this committee with the representative of the Royal College of Surgeons of England. A considerable minority voted against this resolution. Section XX. of the Medical Act of 1858 is. "In case it appear to the General Council that the course of study and examinations to be gone through in order to obtain any such qualification from any such College or body are not such as to secure the possession by persons obtaining such qualification of the requisite knowledge and skill for the efficient practice of their profession, it shall be lawful for such General Council to represent the same to Her Majesty's most honourable Privy Council."

On Dec. 3rd, 1901, when the list of scientific institutions, study at which will be recognised by the Council as entitling a medical student (who has complied with the other conditions) to place his name on the Register, came before the Council I moved as an amendment.—

"That the list of *scientific institutions, other than universities or* schools of medicine, do consist of the teaching institutions where physics, chemistry, and elementary biology are taught, recognised by each licensing body, as stated in the list forwarded each year, provided that the list in each case be accompanied by the statement that after due inspection the licensing body is satisfied that each institution so recognised possesses sufficient laboratory accommodation and appliances for the efficient teaching of the required subjects."

The amendment was seconded by the representative of the Royal College of Surgeons of England, but was not carried. Had the amendment been carried it might have afforded the General Council a means of completing its Register of medical students, a matter to which importance is attached by some members of the Council, but which no longer directly affects the regulations for our Licence. In view of the difficulties into which an attempt to assume powers which do not belong to it has led the General Council it seemed right to take this conciliatory step.

These were the only proceedings directly or indirectly affecting our College. The special meeting of the General Council is to be held at the end of February, 1902

I remain, dear Dr. Liveing, yours faithfully,
NORMAN MOORE.

The quarterly report of the Financial Committee of the College was received and adopted.

A report was received and adopted from the Committee of Management dated Dec. 6th last. This report dealt with three subjects. 1. The teaching of the administration of anæsthetics to candidates for the diploma of L.R C.P. and M.R.C.S. The following now stands as the regulation dealing with the subject :—

> That every candidate who passes the Second Examination of this Board or an examination at a university recognised in lieu of it, on or after May 1st next be required to produce before entering for the Final Examination a certificate of having received at a recognised medical school and hospital instruction in the administration of anæsthetics to the satisfaction of his teachers.

2. The committee also recommend that the North-Western University, Chicago, should be added to the list of universities recognised by the Board at which students might complete the curriculum of professional study and the graduates of which in medicine, on fulfilment of the necessary conditions, might be admitted to the final examination. 3. The fees for the diploma in public health. The committee recommended

has shown that telegraphic messages may be transmitted without the use of wires." A very interesting portion of Sir Lauder Brunton's address referred to the prophet Mahomet, and he invited his hearers to speculate on the question how far the history of the world would have been altered if the prophet had undergone a course of treatment of bromide of potassium. The prophet was described as being subject to attacks in which he fell to the ground foaming at the mouth and bellowing like a bull and he had related himself how he saw sudden visions of light and heard voices. According to Sir Lauder Brunton it was during these epileptic conditions that Mahomet received the utterances which he afterwards wrote partly on skins and partly on sheep's blade-bones from which was formed the Koran. Passing on to discuss the question of Samson's strength, Sir Lauder Brunton took the opportunity of observing that his remarks were in no way intended to ridicule Holy Writ. In his opinion Samson was really an epileptic, and in this connexion he described how he had been shown at an asylum a slight, weakly-looking man, who in a fit of epileptic mania had driven his fist through a two-inch oaken door. Touching the remarkable passage, "Samson said, I will go out and shake myself," it was possible that a parallel might be traced in the preliminary contortions and swayings performed by the howling Dervishes, and Sir Lauder Brunton reminded his audience that the Berserkers could bring themselves into such a state of fury that when they went into battle they required no armour.

## ASYLUM REPORTS.

*Lanark and Govan District Asylum, Kirklands (Report for the year ending April, 1901).*—The average number of patients resident during the year was 179, including 90 males and 89 females. The admissions during the year amounted to 107, and of these 61 were males and 46 were females. Of these 102 were first admissions. Dr. James H. Skeen, the medical superintendent, states in his report that the admissions for the year numbered more than for any year since 1888. "The admissions continue to show a large proportion of cases broken down in health from various and severe forms of bodily ailment. A large number of the cases admitted were *manifestly* beyond hope of cure. ...... 53 of the total [admissions] were of this hopeless class." There was an increase in the number of cases admitted whose insanity was due to alcoholism, either primarily or in conjunction with other causes. Alcoholism thus considered was responsible for 25·7 per cent. of the cases admitted. If the effects of alcoholism in producing weakened offspring were taken into account the damage done by alcoholism would probably have to be regarded as higher. The number of patients discharged as recovered during the year amounted to 23, or 12·8 per cent. of the average number resident. Most of these recoveries have been good, and such discharged patients ought, says Dr. Skeen, to do well in the world if assisted by friends "Our Poor-law authorities do excellent work in helping on such cases ...... but it is seldom such persons care to call again upon an inspector of poor. Is there not work here for some society to help such cases? Discharged prisoners have their future looked after and their life ordered for them if they care. Why not our discharged recovered asylum patients?" Of those discharged unrecovered *the largest* proportion—viz., 58—was transferred to other asylums. The deaths during the year amounted to 16—viz., seven males and nine females, or 8·9 per cent. of the average number resident. Of the deaths one was due to accidental choking, one to phthisis, one to senile decay, two each to epilepsy, cerebral hæmorrhage, and cerebral softening, three to cardiac disease, and the rest to other causes. Two patients escaped during the year, one being a female patient who broke parole The health of the institution has on the whole been good. In concluding his report Dr. Skeen refers to the increase in the maintenance rate. Clothing and food stuffs have risen in price and the increased cost of fuel was another cause of the increase. The Commissioner in Lunacy states in his report that the patients were found to be neatly dressed and efficiently cared for. There was a general absence of excitement among the patients and an air of contentment prevailed. The condition of the dormitories and bedding was very satisfactory. The medical case-books and registers were examined and found to be regularly and accurately kept. The committee of management states in its report that a separate wash-house and laundry are being erected at a cost of between £1600 and £1700. For the first half of the year the rate of board of district patients was fixed at 9*s.* per week, but for the rest of the year it was raised to 9*s.* 6*d.* per patient per week. The weekly charge for out-district patients was fixed at 12*s.* 4*d.* per head.

*Lanark District Asylum, Hartwood (Report for the year ending May 15th, 1901).*—The average number of patients resident during the year was 690 and comprised 365 males and 325 females. The admissions during the year amounted to 205—viz., 107 males and 98 males. Of these 147 were first admissions. Dr. A. Campbell Clark, the medical superintendent, states in his report that among the admissions were 27 patients over the age of 60 years. The number of patients discharged as recovered during the year was 101—viz., 55 males and 46 females, or 14·6 per cent. of the average number resident. The deaths during the year amounted to 47—viz., 28 males and 19 females, or 6·8 per cent. as calculated on the same basis. Of the deaths one was due to shock and collapse from burns, one to fracture of the skull and cerebral concussion, three were due to cerebral and cerebellar hæmorrhage, six to general paralysis of the insane, seven to phthisis and other forms of tuberculosis, nine to cardiac disease with complications, and the rest to other causes. The number of accidents during the year was eight, but of these only two were serious. One patient escaped during the year and could not be re-captured. "The industrial employment of the patients still continues to receive considerable attention, and on an average 72 per cent. of the males and 68 per cent. of the females were industrially employed daily. Of the males 52 per cent. were engaged in garden and field labour." The Commissioner in Lunacy states in his report that every part of the institution was clean and in excellent order both on the male and female sides, the day rooms were bright and most comfortably furnished, the warming of the building was even and excellent, and the medical case-books and registers were carefully and correctly kept. The board of management states in its report that the weekly charge of maintenance for district pauper patients had been kept at 8*s.* 9*d.* per head, notwithstanding the considerable rise in the price of commodities.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8238 births and 5115 deaths were registered during the week ending Feb. 1st. The annual rate of mortality in these towns, which had been 18·2, 17·7, and 17·7 per 1000 in the three preceding weeks, rose again last week to 17·9 per 1000. In London the death-rate was 18·8 per 1000, while it averaged 17·6 in the 75 other large towns. The lowest death-rates in these towns were 7·2 in York, 9·2 in Burton-upon-Trent, 9·3 in Wallasey, 9·7 in Hornsey, 9·8 in Walthamstow and in Barrow-in-Furness, and 10·2 in Birkenhead; the highest rates were 23·6 in Halifax, 24·3 in St. Helens, 25·0 in Rhondda, 25·9 in Merthyr Tydfil, 26·1 in Ipswich, 26·5 in Newport (Mon.), and 30·3 in Great Yarmouth. The 5115 deaths in these towns last week included 444 which were referred to the principal zymotic diseases, against 534 and 512 in the two preceding weeks; of these 101 resulted from whooping-cough, 85 from measles, 85 from diphtheria, 60 from scarlet fever, 43 from small-pox, 39 from diarrhœa, and 31 from "fever" (principally enteric). No death from any of these diseases was registered last week in 14 of the large towns, including Hornsey, Walthamstow, Southampton, Norwich, Derby, York, and eight other smaller towns; the highest zymotic death-rates were recorded in Willesden, East Ham, West Bromwich, St. Helens, Middlesbrough, Stockton-on-Tees, West Hartlepool, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Northampton and in St. Helens; from scarlet fever in Newcastle and in South Shields; from diphtheria in Willesden, East Ham, West Hartlepool, Cardiff, and Merthyr Tydfil; from whooping-cough in Aston Manor, Leicester, Liverpool, and West Hartlepool; from "fever" in St. Helens; and from diarrhœa in West Bromwich and Middlesbrough. 39 fatal cases of small-pox were registered in London, two in Willesden, one in Tottenham, and one in West Ham, but the officers of the Royal Army Medical Corps in their fine mess-room.

The following list shows the positions of the officers who obtained commissions:—

### INDIAN MEDICAL SERVICE.

List of surgeons-on-probation who were successful at both the London and Netley examinations. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—

** Gained the Martin Memorial Medal.

†† Gained the Second Montefiore Prize of £7 7s., and the Prize in Pathology.

‡‡ Gained the First Montefiore Prize of £21 and Medal.

## STATISTICAL REPORT OF THE HEALTH OF THE NAVY FOR 1900.[1]

WE may congratulate Sir Henry F. Norbury, K.C.B., the Director-General of the Medical Department of the Royal Navy, on the preparation and issue of an unusually good and interesting report concerning the health of the navy and the work done by the officers of his department. To the general reader Parliamentary publications, and especially those dealing with statistics, cannot at best be regarded as an enticing form of literature, however interesting they may prove to statisticians or however necessary they may be for the information of the two Houses of Parliament. While every complaint to which the seamen of the Royal Navy are liable is, for statistical purposes, recorded in this report, there is besides a good deal which is well worth reading to be found in the numerous papers published in the appendix, and it is to these rather than to the figures and ratios which form one of the most prominent features of the report itself that our readers will probably turn.

To begin with the general aspect of the health of the navy from a statistical point of view we gather from the introductory summary of results that after making allowance for exceptional conditions on the Cape of Good Hope, the West Coast of Africa, and the China stations, the health returns for the total force serving afloat may be regarded as satisfactory. To touch upon some of the points we may say that the death-rate per 1000 was 7 27, showing an increase of 1 86 per 1000 as compared with the previous year, and of 2 09 in comparison with the ratio of the last three years. The stations which exhibit the highest death-rates are the Cape of Good Hope and West Coast of Africa (20 03), China (17·34), and the East Indies (13 92). The lowest mortality was on the North America and the West Indies station—viz., 3 59. 378 cases of wounds in action are recorded. Of these, 18 cases with five deaths occurred in South Africa, and 360 cases with 69 fatalities in China. These two stations are responsible for a large increase in the number of cases of enteric fever and dysentery, the deaths from which diseases in the total force numbered respectively 124 and 27, as compared with 41 and 12 in 1899.

The total force serving afloat in 1900 was 95,830. The total number of cases of disease and injury entered on the sick list was 84,550, which is in the ratio of 882·29 per 1000—an increase as compared with the previous years but a decrease of 11·22 per 1000 as compared with the average ratio of the last three years. There is a reduction in the ratio of cases as compared with 1899 on the Home, the Pacific, the Cape of Good Hope, and the West Coast of Africa and the Australia stations, but an increase in the remaining stations. The lowest sick-rate was on the South-East Coast of America station and the highest on the China station.

The invaliding ratio of the total force is 35·83 per 1000, which shows a considerable increase, the highest rate being on the China station (54 52 per 1000). The total number of men invalided was 3434, of whom 3124 were for disease and 310 for injury. The ratio of invaliding for disease alone was 32·59 per 1000 and for injury 3·23 per 1000. A new table has been added this year (page 16) showing the disease or injury together with the age and length of service of the persons finally invalided from the service. The death ratio per 1000 was, as we have said, 7·27, of which 4·96 were from diseases.

As regards general diseases we may mention that there were 464 entries for enteric fever with 98 invalidings and 124 deaths, attributable in great part to the prevalence of this disease in those places where warlike operations were in progress—China, South Africa, and the West Coast of Africa. There were 13 cases of small-pox altogether (one of which was fatal). Five out of six cases of cerebro-spinal fever—all on the Home station—terminated fatally. Mediterranean fever gave an increased number of cases as compared with 1899. Under the head of "dysentery" there were 420 cases returned with 79 invalidings and 27 deaths—the increased incidence of the disease being due to the same causes that augmented the totals of enteric fever—viz., military operations in South Africa and China.

The statistical information grouped in the section "Hospitals" (page 19, *et seq.*) is interesting as illustrative of the nature and results of the diseases and injuries treated in naval hospital practice; and the notes and remarks on the different stations (pp. 28 to 65) may be referred to as containing many interesting and instructive observations—especially those on the Mediterranean, the Cape of Good Hope, the West Coast of Africa, and the China stations.

The Appendix to the report strikes us as a whole as being unusually good, several of the papers in particular being excellent and containing information of a practical and scientific character which it will well repay medical officers of our public services to read. We had marked many passages in some of these papers for reference and remark, but we must content ourselves by simply expressing our opinion in regard to them and to the report and its appendix as a whole. To those of our readers who are interested in matters of naval and military medicine, hygiene, climatology, and medical experiences in modern warfare we would commend such papers as "Some Observations on Recruiting," by Fleet Surgeon E. H. Williams; "Malarial Fever on the Zambesi and Shiré Rivers," by Surgeon R. T. Gilmour; "Medical Notes of the Western Naval Brigade—South Africa, 1899–1900," by Deputy Inspector-General James Porter, R.N.; "The Naval Brigade in North China," by Staff Surgeon Edward B. Pickthorn; and the paper on a "Case of Death from Syncope Caused by Caisson Disease," by Fleet Surgeon Archibald McKinlay. The reports by Deputy Inspector-General Porter and Staff Surgeon Pickthorn are full of interesting descriptions and instructive medical details.

## SPIRITUALISM AND HALLUCINATIONS.

SIR LAUDER BRUNTON, in the course of a fascinating address delivered before the British Association of Nurses at Orchard-street, London, W., on Jan. 21st, stated his belief that an explanation of the action of one mind upon another when two persons are sundered by a considerable distance can be looked for in the direction of "brain waves passing from one to the other in some sort the same way as Marconi

"Audi alteram partem."

## A POINT IN THE ETIOLOGY OF ALCOHOLIC PERIPHERAL NEURITIS.

*To the Editors of* THE LANCET.

SIRS,—The reappearance of cases of chronic arsenical poisoning amongst beer-drinkers occurring a fairly considerable time after the Manchester epidemic must be regarded with great interest by those who now maintain that all cases of so-called "alcoholic" peripheral neuritis are not alcoholic but arsenical in origin.

In October, 1901, three persons suffering from the effects of chronic arsenical poisoning were admitted to the Halifax Union Poor-law Hospital. During January, 1902, four cases were admitted. These numbers, of course, compared with those of 1900 are very small. All the cases are of recent date and vary much in the severity of their symptoms, which in all cases are quite characteristic of chronic arsenical poisoning. Sufficient arsenic was found in the Halifax beer by Mr. Alfred Henry Allen of Sheffield, public analyst for the West Riding of Yorkshire, to account for these symptoms of arsenical poisoning. He found $\frac{1}{18}$th, $\frac{1}{24}$th, and $\frac{1}{16}$th of a grain per gallon of arsenic in the three samples of beer examined by him. Arsenic has been obtained from the urine of some of the patients, and in the case of the man who died it was detected in the tissues. In the stomach and two or three feet of small intestine Mr. Allen obtained indications of arsenic representing not more than $\frac{1}{200}$th part of a grain. In three ounces of liver he found not more than $\frac{1}{100}$th part of a grain. These quantities, though but small, would work out fairly large were the weights of the whole organs taken into consideration. A person would only be required to drink eight half-pints of the worst beer in order to obtain an average medicinal dose of arsenic ($\frac{1}{30}$th part of a grain), but here all are admittedly heavy drinkers and not likely to stop at that quantity.

With beer containing arsenic in injurious quantities, a history of the patients being heavy drinkers, and the clinical symptoms of chronic arsenical poisoning, it was not difficult to arrive at a correct diagnosis. Before the Manchester epidemic it is quite easy to see that a correct diagnosis might not have been made. It is obvious that arsenic as a causal agent in the production of "alcoholic" peripheral neuritis has been overlooked for the last 20 years, its share in the production being only found out when the quantity of arsenic contained in the beer was in such large amounts as to cause the increase in numbers of cases of peripheral neuritis to assume epidemic proportions. The most likely way in which arsenic gains access to beer, now that the brewing sugars are pure, is through the malt. This source will always have been there as long as the present methods of drying malt in the kilns have been used, providing fuel containing arsenic has been used. The grain in the kiln is exposed to the products of combustion of either coke or anthracite coal. Some cokes are known to contain quite large amounts of arsenic. If such fuel is being used then that used in the north must contain a much larger quantity of arsenic than that used in the south, thus accounting for the outbreak here and the rarity of the disease in the south. The susceptibility of different persons to the action of arsenic must also be taken into account as well as the conditions under which a man lives. With some persons very small medicinal doses of arsenic soon produce serious symptoms. Persons doing heavy work do not seem to be very susceptible to the influence of arsenic; this will account for the rarity of arsenical beer-poisoning amongst brewers' draymen, many of whom drink far more beer during the course of the day's work than an habitual drunkard. In the above cases the persons have not worked or their work has been of a sedentary character.

In Manchester and district since the use of brewing sugars containing arsenic has been discontinued, peripheral neuritis and alcoholic hearts have almost vanished, and from what I can hear from hospitals in surrounding towns there has been a similar and striking diminution in the number of cases of peripheral neuritis. The finding of arsenic as the factor in the production of the Manchester epidemic caused many to doubt the action of alcohol itself as the chief factor in the causation of peripheral neuritis, but the above facts prove undoubtedly, or at any rate go a long way towards proving, that the so-called "alcoholic" peripheral neuritis is not alcoholic but arsenical in origin. If this be so then it is not surprising that the cases of peripheral neuritis are few, for they will now be confined to the heavy drinkers and those specially susceptible to the action of arsenic.—I am, Sirs, yours faithfully,

J. F. HODGSON, M.B., Ch.B. Vict.,
Resident Medical Officer, Halifax Union Poor-law Hospital.
Feb. 3rd, 1902.

## THE SANATORIUM TREATMENT OF CONSUMPTION.

*To the Editors of* THE LANCET.

SIRS,—It afforded me considerable pleasure to see that Mr. E. D. Marriott had apparently realised the inaccuracy of his statement that the financial problem involved in the erection of sanatoriums for the treatment of consumption was absolutely insoluble, and that he had altered his antagonistic attitude to the extent of saying "these institutions may form one of the lines along which we have to work." He, however, returned to the charge by repeating his assertions that the "atmosphere" of sanatoriums is more likely to lead to secondary infection than the "atmosphere" of ordinary houses, and that sanatorium treatment does not involve anything which cannot be carried out at home. Mere repetition of an assertion, however, even when couched in somewhat exaggerated language, does not necessarily constitute proof. I hesitate to trespass further on your space by referring to well-known facts, as it seems almost hopeless to attempt to convert your correspondent in view of his declaration that he "neither has nor wants to have anything to do with the attitude of Germany in this matter," although the bulk of our knowledge on sanatoriums is derived from the 40 years' experience which our neighbours have had on this subject.

As regards the question of liability of secondary infection at sanatoriums I would call Mr. Marriott's attention to a number of experiments which have been carried out in Germany, America, and this country upon the infectivity of the dust found in sanatoriums and in houses in which a consumptive has lodged. These experiments were carefully considered by the members of the council of the National Association for the Prevention of Tuberculosis before they adopted the following resolution:—

> Having understood that apprehensions have been entertained as to the spread of consumption from sanatoria established for the treatment of this disease, the Council of the National Association for the Prevention of Consumption desire to express their opinion that there is no danger of communication from any well-conducted hospital for consumption or from any sanatorium where the open air treatment for this disease is properly carried out; and, further, that the inhabitants of houses in the immediate neighbourhood of such institutions are perfectly safe from local propagation from this source.

The council of this association is composed of eminent members of the medical profession and their opinion is entitled to some weight. I may, perhaps, be allowed to quote one or two of these experiments. Cornet in his work, 13 years ago, on this subject showed that in most cases where tuberculous patients, or a single patient, occupied a room of an ordinary house, the dust from this source contained tubercle bacilli which were sufficiently virulent to kill guinea-pigs. Dr. Biggs of New York and Dr. H. Coates of Manchester have confirmed this statement. Dr. Coates recently found virulent tubercle bacilli in over 68 per cent. of dirty houses and in 50 per cent. of clean houses.[1] On the other hand Dr. I. Hance of the Adirondack Cottage Sanatorium proved by the inoculation of guinea-pigs that out of 17 cottages, inhabited by consumptives for so long a period as 10 years, 16 were absolutely free from infectious material. In the seventeenth cottage a patient had disobeyed instructions and had expectorated wherever convenient. Dr. Achtermann, when he was connected with the Brehmer Sanatorium, tested by means of inoculation the dust from the corridors, recreation rooms, water-closets, and patients' bedrooms during a period which extended over several years. Only once did he find evidence of tubercle bacilli and then from dust on a washing board where a sputum flask had stood. These figures prove, if they prove nothing else, that not one in any other of the 76 large towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 873, 877, and 870 at the end of the three preceding weeks, had risen again to 1136 on Saturday, Feb. 1st; 499 new cases were admitted during the week, against 306, 213, and 204 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital was 2555, against numbers decreasing from 3137 to 2658 on the five preceding Saturdays; 226 new cases were admitted during the week, against 250, 288, and 299 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 366, 307, and 357 in the three preceding weeks, further rose last week to 374, but were 69 below the corrected average. The causes of 55, or 1 1 per cent., of the deaths in the 76 large towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Leeds, Newcastle, and 44 other smaller towns; the largest proportions of uncertified deaths were registered in Willesden, Birmingham, Liverpool, St. Helens, and Blackburn.

---

[1] The percentages were probably higher, as in some cases the dust killed the guinea-pigs before it was possible to ascertain the presence of tuberculosis.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·8 and 20·3 per 1000 in the two preceding weeks, increased again to 21·8 per 1000 during the week ending Feb. 1st, and exceeded by 3·9 per 1000 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·9 in Perth and 18 6 in Paisley to 23·1 in Aberdeen and 23·2 in Glasgow. The 704 deaths in these towns included 23 which were referred to measles, 19 to whooping-cough, eight to diarrhœa, seven to scarlet fever, five to diphtheria, three to "fever," and one to small-pox. In all 66 deaths resulted from these principal zymotic diseases last week, against 56, 63, and 76 in the three preceding weeks. These 66 deaths were equal to an annual rate of 2 0 per 1000, which was 0·4 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 23 and 31 in the two preceding weeks, declined again last week to 23, of which 16 were registered in Glasgow and five in Dundee. The deaths from whooping-cough, which had been five, 11, and 13 in the three preceding weeks, further increased to 19 last week, and included 12 in Glasgow, four in Aberdeen, and two in Leith. The fatal cases of diarrhœa, which had been 13 and 20 in the two preceding weeks, declined again to eight last week, of which two were registered in Glasgow and two in Dundee. The deaths from scarlet fever, which had been six and four in the two preceding weeks, rose again to seven last week, and included five in Glasgow and two in Greenock. The fatal cases of diphtheria, which had been six and five in the two preceding weeks, were again five last week, and included two in Glasgow, where two of the three deaths from "fever" and the fatal case of small-pox were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 176 and 128 in the two preceding weeks, rose again to 141 last week, and were 18 above the number in the corresponding period of last year. The causes of 37, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·0, 23·4, and 20·9 per 1000 in the three preceding weeks, rose again to 22·7 per 1000 during the week ending Feb. 1st. During the past four weeks the death-rate has averaged 22·0 per 1000, the rates during the same period being 18·3 in London and 18·7 in Edinburgh. The 165 deaths of persons belonging to Dublin registered during the week under notice showed an excess over the number in the preceding week, and included four which were referred to the principal zymotic diseases, against 10, six, and eight in the three preceding weeks; of these one resulted from measles, one from scarlet fever, one from diphtheria, and one from whooping-cough. These four deaths were equal to an annual rate of 0 6 per 1000, the zymotic death-rates during the same period being 1 8 in London and 0·3 in Edinburgh. The 165 deaths in Dublin last week included 20 of children under one year of age and 46 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight decline from the numbers recorded in the preceding week. Four inquest cases and two deaths from violence were registered; and 55, or one-third, of the deaths occurred in public institutions. The causes of five, or more than 3 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

Staff Surgeon Ernest Edward Bray has been placed on the retired list at his own request.

The following appointments are notified:—Surgeons: A. La T. Darley to the *Britannia* for the *Racer*; J. N. Robertson to the *Goldfinch*; G. C. C. Ross to the *Magnificent*; W. L. Martin to the *Tamar*; and H. R. H. Denny to the *Vivid* for the *Thistle*.

### ROYAL ARMY MEDICAL CORPS.

Colonel N. B. Major, from half-pay, to be Colonel (dated Jan. 4th, 1902). Lieutenant-Colonel E. H. Joynt is placed on retired pay (dated Jan. 19th, 1902). Civil Surgeon Leonard Cotterill to be Lieutenant (dated Dec. 5th, 1901).

Colonel R. C. Eaton, Officiating Principal Medical Officer, Bombay command, is granted six months' leave to proceed to Genoa for the benefit of his health. Captain C. E. Pollock is selected for duty in the Scottish District.

### VOLUNTEER CORPS.

*Rifle*: The Queen's Rifle Volunteer Brigade, the Royal Scots (Lothian Regiment): Robert Abernethy to be Surgeon-Lieutenant. 1st (Brecknockshire) Volunteer Battalion the South Wales Borderers: Surgeon-Lieutenant H. Williams resigns his commission. 1st Volunteer Battalion the Dorsetshire Regiment: Surgeon-Lieutenant W. G. Brett to be Surgeon-Captain.

### VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: David William Stevens Muir to be Surgeon-Lieutenant.

### SOUTH AFRICAN WAR NOTES.

Lieutenant A. O. B. Wroughton, R.A.M.C., is reported to be slightly improved (Feb. 1st).

Civil Surgeon Bensusan is reported to be improving (Feb. 2nd).

Civil Surgeon Fort, no change (Feb. 1st).

Civil Surgeon Penn is reported to be a little better (Feb. 1st).

Civil Surgeon Armstrong is reported somewhat improved (Feb. 2nd).

### THE ADVISORY BOARD.

In commenting upon the War Office proposals for the carrying out of the work of the Advisory Board for the Army Medical Service the *Army and Navy Gazette* makes some pertinent remarks. According to the constitution of the board junior officers will sit and deliberate on the promotion of their seniors. There are two comparatively junior officer of the Royal Army Medical Corps on the board—a lieutenant-colonel and a major. Can it be right, asks our service contemporary, that these officers should be allowed a voice in the question, for instance, of the promotion of their seniors, or, for the matter of that, in any detail in which the acts of their seniors are concerned? It is contrary to the rules of the service and the precedent is a dangerous one.

INCONSISTENCY OF A "CONSCIENTIOUS OBJECTOR."—At the Exeter Police-court on Jan. 27th a parent applied for a certificate of exemption from vaccination for his child, stating that several members of his family had suffered from the effects of vaccination. The mayor, who was on the bench, asked the man if he had a servant who contracted small-pox and his child had been in company with the servant what he would do under the circumstances. The conscientious objector promptly replied that he would have the child vaccinated. The magistrates did not grant him an exemption order.

strengthened by the fact that vaccination ran an ordinary course. I suspect that not a few people who think themselves *immune through having already had an attack of* small-pox are buoying themselves up with a false belief, having had chicken-pox and not small-pox. The only means of obtaining any degree of assurance as to immunity to small-pox is to submit to vaccination and see the result.

I am, Sirs, yours faithfully,
J. T. C. NASH, M.D. Edin., D.P.H. Cantab.,
Medical Officer of Health.
Southend-on Sea, Jan. 28th, 1902.

# FIRST AID FOR PRIMARY HÆMORRHAGE: THE WRONG INSTRUCTION GIVEN TO AMBULANCE CLASSES.

*To the Editors of* THE LANCET.

SIRS,—I have read with the greatest gratification the leading article in THE LANCET of Jan. 25th, p. 238, and as I have been connected with the ambulance movement ever since its commencement I can thoroughly endorse all you say. The teaching of the St. John Ambulance Association is excellent in every way and the treatment of hæmorrhage, the most important of all matters which the first-aid student has to deal with, is thoroughly taught. The efficiency of the men in the St. John Ambulance Brigade is tested annually and no man is allowed on duty in the streets of London except those who have passed the re-qualifying examination; so the general public may know that in the men of this brigade they have those upon whom they can thoroughly rely. With the general public who hold certificates of ambulance work, however, no such precaution is taken; they attend ambulance lectures and afterwards fail to keep up their knowledge, and relying upon the fact of having once gone through a course of instruction, sometimes several years ago, presume to render "first aid" on the strength of what has been largely forgotten.

I have suggested, and I hope it may sooner or later be adopted, that students who take an interest in this work and have presented themselves for examination on three occasions shall have further power of periodical re-examination if they desire to keep themselves efficient in this, one of the most useful subjects which they can learn. The first-aid movement has rendered incalculable benefit to many a sufferer and to judge or to condemn it on account of one or two mistakes in the face of the numerous benefits conferred upon so many would be palpably unjust. The remedy lies in greater severity in the matter of examinations, as to whom certificates of efficiency are granted, and in the necessity of making those certificates which are gained only applicable to one year, or at the most two years, from the date of issue.

I am, Sirs, yours obediently,
SAMUEL OSBORN,
Chief Surgeon, Metropolitan Corps, St. John Ambulance Brigade.
Feb. 3rd, 1902.

*To the Editors of* THE LANCET.

SIRS,—If Mr. Walter G Spencer will kindly re-peruse my letter in THE LANCET of Jan. 18th, p. 194, he will see that I do not ask him to say what *he* would have done but "what the comrades ought to have done" in the sad case which I quoted. Mr. Spencer says: "It must be some kind of very large chaff-cutter to draw in *both* a man's legs—they would first be crushed by the rollers before being cut off. The result would not be different from a railway accident. Owing to the shock and the crushed ends of the arteries there would be no great arterial hæmorrhage." But the poor man died from hæmorrhage. We know that Mr Spencer is an excellent surgeon and we feel sure that if he had been present "the rapid and efficient application of a tourniquet" would have been accomplished, and further, I believe that the man's life would have been saved. Mr. Spencer advises "that the instruction to an elementary class as regards such an accident should be that elevation and local pressure is to be applied at once and the tourniquet reserved until the patient is anæsthetised and the surgeon ready to explore the injury"; are there accidents which do require "the rapid and efficient application of a tourniquet" to save life? The St. John Ambulance Association says that there are, and you, Sirs, in your excellent leading article on this subject in THE LANCET of Jan. 25th, p. 238, also say there are; your words are pointed and cannot be misunderstood. You write: "*To solve the problem of the correct treatment of hæmorrhage we must* go back to general surgical principles. In the first place, we must distinguish the hæmorrhage after wounds of vessels in their continuity from that due to the complete removal of a part of a limb. In the latter case there is no room for doubt that a firmly applied tourniquet is the only method of rapidly controlling the extensive hæmorrhage which is generally present." It follows, therefore, that ambulance pupils *must be taught* how to apply a tourniquet rapidly and efficiently. Although I believe similar cases to the one referred to are not so infrequent as Mr. Spencer appears to me to think, the frequency has nothing to do with the matter. First-aiders have saved many a life, and may they continue their noble work, notwithstanding the discouragement which they have received from Mr. Spencer and a few others.

I am, Sirs, yours faithfully,
Ongar, Jan. 28th, 1902. J. B. G. GIDLEY-MOORE.

# THE TREATMENT OF METRORRHAGIA.

*To the Editors of* THE LANCET.

SIRS,—In his recent paper on the Uterine Curette, read before the Liverpool Medical Institution, an abstract of which appeared in THE LANCET of Jan. 25th, p. 229, Dr. H. Briggs adopted a very pessimistic attitude towards curettage—a proceeding which is frequently disappointing in its results to all gynæcologists. He mentioned one case of a woman who consulted him for a purulent condition of the uterus whom he had advised to relinquish local in favour of general hygienic treatment. In another case, where metrorrhagia recurred after curettage, he removed the uterus, there being no evidence brought before us of the existence of malignant or other grave disease. The impression I received from his paper was that Dr. Briggs was feeling his way to hysterectomy in the treatment of endometritis, or rather of metrorrhagia. The profession will be interested to learn whether this impression is a correct one, and how far Dr. Briggs suggests we should go in radical treatment for such conditions. The responsibility of surgeons in such cases is a very grave one, and the limits of justifiable operative treatment are, in my opinion, soon reached.

I am, Sirs, yours faithfully,
Liverpool, Jan. 25th, 1902. GEORGE A. HAWKINS-AMBLER.

# DEFICIENCY OF THE BILE-SALTS THE PROBABLE PREDISPOSING FACTOR IN TUBERCULOSIS AND FATTY FOODS CONTRA-INDICATED IN ITS TREATMENT.

*To the Editors of* THE LANCET.

SIRS,—I have been for some years past of the opinion that the "bile-salts" played an important rôle with regard to tuberculosis, and now that the world is all agog with the subject of tuberculosis I wish to place my views and the results of my observations and deductions before the profession. It is well known that "tubercle bacilli" are difficult to grow on ordinary media, but by the addition of glycerine to the media a luxuriant growth is produced. I made a series of cultivations of tubercle bacilli in glycerine agar-agar and then endeavoured to cultivate them in glycerine agar-agar impregnated with the "bile-salts" (glycocholate and taurocholate of sodium). In many cases I failed to get any growth at all, and when I did succeed the growth was very feeble indeed. I repeated this experiment with several other media with the same result. Encouraged by these results I determined to try the effects of giving pig bile, "which most nearly resembles human bile," in large doses to a well-pronounced case of pulmonary tuberculosis; and bearing in mind the fact that "bile" in the intestines saponifies as well as emulsifies fats and oils and produces glycerine as a by-product, I prohibited the use of all fatty foods, including cod-liver oil, cream, &c., and kept the patient on a strictly but abundant nitrogenous diet with the idea of starving the "tubercle bacilli" of its congenial pabulum—i.e., "glycerine." The improvement was very marked, the cough improved, the evening temperature dropped, the night sweats discontinued, and a remarkable change occurred in the facial in sanatoriums more efficient means are adopted for the destruction of tubercle bacilli than in ordinary houses. The principles of careful disinfection are not readily taken up by the public and one of the many virtues of the sanatorium method of treatment is that it helps to educate people in this respect. I refrain in consideration of your space from going into further detail, but if your correspondent is still unconvinced I would refer him to the original papers on this subject and to Dr. Rufenacht Walters's and others' books on sanatoriums.

Mr. Marriott reiterates his statement that isolation fever hospitals breed secondary infection and post-scarlatinal diphtheria, and that therefore sanatoriums for consumption must be responsible for something of the same kind. He is convinced of this because "secondary infection and post-scarlatinal diphtheria never obtain in ordinary houses." Your correspondent's experience must have been a singularly fortunate one, for it is no uncommon thing in London to see children who have fallen victims to secondary infection or diphtheria after an attack of scarlet fever, although they have been treated in their own homes. I should like to say more concerning these isolation hospitals, but this question is somewhat beside the point. An *a priori* line of argument is seldom convincing, and it would be more satisfactory if Mr. Marriott brought forward instances of secondary infection which have occurred in sanatoriums for tuberculosis. If such cases have occurred he should have no difficulty in producing them, seeing that this form of treatment has been in existence for 40 years.

Your correspondent further asserts that the personal factor of a patient cannot receive the same attention in a sanatorium as at home. Is this in accordance with fact? At an efficient institution of this kind each patient is seen professionally at least three times a day, and also takes his meals under the immediate supervision of the physician. In addition to this, every detail of his life, such as the amount of exercise he may take, the literature he may read, and the like, receives the most anxious and painstaking consideration. It is this careful attention to an infinity of detail which is one of the most characteristic features of sanatorium treatment; it is more essential than the nature of the building, but I can see no reason why Mr. Marriott, who champions good sanitation, should object to the institution being made as healthy as possible. The necessary discipline of such treatment as the above cannot in the nature of things be carried out at home until the patient's disease has become quiescent and he has learnt the true value of its details. 40 years' experience has shown that when the attempt is made to treat a case from the first at home it not infrequently fails.

Dr. Walther, who prefers severe cases, brings about arrest of the disease in 30 per cent. (Knopf) of his patients, and these continue to do well after they have left the Nordrach Colonie He only fails to obtain considerable improvement in 5 per cent of his cases, and his world-wide reputation, to which your correspondent refers, is due to the enormous amount of attention he devotes to the personal factor of his patients. Other efficient sanatoriums give equally satisfactory results. Can Mr. Marriott show anything to equal these figures by home treatment in all stages of the disease?

No one will deny that good sanitation is the best weapon we have for the *prevention* of tuberculosis and is largely responsible for the diminution in the mortality from this disease in the last 60 years, a period which coincides, as Dr. J. E. Pollock has pointed out, with the time during which the Brompton Hospital has been in existence I cannot, however, agree with Mr Marriott that in treating those already afflicted with the disease we should deny them the form of treatment which on 40 odd years' experience has been shown, not, it is true, to cure every case, but to be the best with which we are acquainted. I am, Sirs, yours faithfully,

Brook-street, W, Jan. 29th, 1902. ARTHUR LATHAM.

---

## IS SALT A PROBABLE CAUSE OF CANCER?

*To the Editors of* THE LANCET.

SIRS,—The letter of Mr. R. D'Oyly Noble in THE LANCET of Jan. 25th, p. 261, is founded upon an assertion which I think is incorrect. Having admitted that I have conclusively proved in my paper upon this subject, a short extract of which was published in THE LANCET of Dec. 7th, 1901, p. 1578, that in those sections of the country in which a very large amount of bacon and ham is consumed, as in the Malton and Pickering cancer field, the disease of cancer is most prevalent, he suggests that the cause is not an excessive amount of salt consumed—along with, I suppose, an unnecessary amount of animal food—but that it is owing to the bacon or ham being itself unclean owing to American pigs being habitually fed on the entrails and blood of slaughtered animals, many of which are infected by diseases of a cancerous nature. I think this is a gross libel upon the Americans; but even if it were true—which it cannot be, for they rear their own pigs—there would be no harm in letting pigs eat the entrails of slaughtered animals. It is not a nice idea, but hens are commonly given in this country chopped sheep's entrails. Nothing is found to make them lay eggs better and neither the eggs nor the hens are infected from the food. We manure our corn with the most offensive dung, but the wheat is quite pure. In growing celery the dung comes into close contact with the plants and they are not injured thereby. We ourselves habitually eat semi-putrid game, previously cooked I admit, but it cannot be called clean food for all that. I do not believe for a moment that the diseases of a cancerous nature spoken of are such—and, moreover, if the pigs eat the entrails, who eats the cancerous meat?

If I could persuade the Editors of THE LANCET to publish my paper in full some misconceptions about it would disappear, especially that I founded the theory in any way upon the comparative immunity of the Jews from cancer. I merely mentioned this as one of three points which first drew my attention to the subject, and after further investigation, although it has confirmed the opinion that Jewesses are almost exempt from cancer of the uterus and that Jews are less liable to cancer generally than we are, I now doubt whether this has any connexion with the ingestion of salt. Whether, however, this is so or not does not affect my argument in the least, as it was not founded upon it

What I complain of in the present ideas about the investigation of cancer is that so-called committees are suggested and money is asked for to make further researches when the materials are already at hand to come to a pretty definite conclusion Almost hundreds of facts are known about the disease, but these facts are not utilised by comparing one with another. A criminal is being looked for who is destroying our population in a most deadly and painful manner. Why not see what circumstance or object is common to all cases of cancer? This is precisely how a detective would set to work in a criminal investigation. If in a number of burglaries a certain man could be proved to be invariably close to the spot in every instance, although not actually seen to do the deed, I think almost any jury would convict him. My point is, that whenever cancer exists two at least of four factors must be present. One of these is salt in some excess, the other is a local irritant. Of the other two factors—viz., over-feeding and effeteness—one is usually present, but not necessarily. I think that a small amount of salt is necessary to health, but if taken in the large amount it usually is, along with a good deal of meat, it is dangerous as age advances, and highly dangerous if the life is an indolent one and passed much indoors. On the other hand, I think salt quite inoperative unless with the coöperation of some local irritant, such as the sharp edge of a stump in the mouth or an unglazed tobacco-pipe. There is one most remarkable instance of a local irritant mentioned in my full paper. The natives of Cashmere carry a small brazier of hot coals pressed against the skin of the abdomen to keep themselves warm in lieu of sufficient clothing in winter. This causes cancer of the skin. They take a large amount of salt, and salt, rice, peas, and wheat are the only things common to them and to us; everything else in food and general environment is different. I am, Sirs, yours faithfully,

Leeds, Jan. 24th, 1902. JAMES BRAITHWAITE.

---

## SECOND ATTACKS OF SMALL-POX.

*To the Editors of* THE LANCET.

SIRS,—In support of your remarks in THE LANCET of Jan. 25th, p. 248, on this subject, I may say that recently one of my sanitary inspectors said that he did not think that he need be revaccinated as he had had small-pox and had been kept from work for three months in consequence. As his face was unscarred I questioned him as to symptoms, distribution of eruption, &c., and came to the conclusion that his supposed attack of small-pox had been one of chicken-pox. This opinion was to do the same in respect of swine fever. The law, however, is the law, and our correspondent, as far as he has tested it, has found it against him. We shall be pleased to hear what other public vaccinators may think of the position, as the law might be amended in response to a vigorous expression of opinion.—ED. L.

## ROYAL MEDICAL BENEVOLENT COLLEGE.

*To the Editors of* THE LANCET.

SIRS,—Under the provisions of the will of the late Mr. France the Council of the Royal Medical Benevolent College will proceed to elect at their meeting on April 2nd eight aged and necessitous medical practitioners to annuities of the value of £30. Particulars can be obtained from the secretary at the office of the College, 37, Soho-square, W.

I am, Sirs, yours faithfully,
C. HOLMAN, Treasurer.

37, Soho square, London, W., Feb. 3rd, 1902.

## THE EDINBURGH SCHEME FOR A PSYCHIATRIC CLINIQUE.

*To the Editors of* THE LANCET.

SIRS,—In your leading article on "The Edinburgh Scheme for a Psychiatric Clinique" in THE LANCET of Feb 1st, p. 318, you appear to bestow your unqualified blessing upon the London County Council scheme for the establishment of reception houses for the preliminary treatment of the insane. You apparently are unaware that each Poor-law district in London possesses one or more such reception houses in the shape of fully-equipped and up-to-date mental wards attached to the various infirmaries. The buildings belonging to the Lewisham Infirmary consist of a handsome separate block, accommodating 11 male and 11 female patients, and fitted with all modern appliances. The system which upon my recommendation has been carried out by the local magistrates and guardians of the poor is to detain all cases of alleged lunacy in the mental block for a variable period before deciding upon their transfer to an asylum. The most gratifying results have attended our treatment. Out of 1382 cases treated during the past seven years 742 have been discharged cured, 144 have died, 20 have been sent to imbecile establishments, and only 476 have been sent to asylums. The majority of the deaths were cases of senile dementia.

The objections to the London County Council scheme are many. The change will simply be from one authority to another, but it will involve the enormous expenditure associated with the building and staffing of at least four large institutions. I anticipate that the buildings alone would cost over £500,000. The expense of collecting the patients from the wide area feeding each reception house must be considered. There is also the hardship inflicted upon the relatives and friends of the patients by making them travel long distances for the purposes of visiting, &c.; but the strongest argument against the proposed change is the stigma of "lunacy" which will rest upon the reputation of every patient who enters a reception house. Under existing arrangements no such stigma is attached, the patient has simply "gone into the infirmary," a circumstance to which no disgrace is attached There is an adage which asserts "that because the kittens were born in the oven it did not make them loaves of bread," but it will be found that by whatever euphemistic title the reception houses may be called they will be lunatic asylums to the public, and it is only those whose work brings them into contact with lunacy who can appreciate the fearful stain left upon a bread-winner and his family by the circumstance that he has been "sent to an asylum." In conclusion, I have no hesitation in asserting that the "early" mental cases are treated efficiently and thoroughly in the London infirmaries and that any change would be for the worse and not for the better. If there be a demand for the utilisation of these unfortunate cases for clinical study, the medical staff of the infirmaries is thoroughly capable of giving that instruction. Your statement that "the expense and moral cruelty of sending to an asylum those early cases which only required a few days' care ...... led to the suggestion of receiving houses" is incorrect, as for many years past the London county asylums have been quite full and it is rare to obtain a vacancy until the lapse of a fortnight and often a month after application.

I am, Sirs, yours faithfully,
F. S. TOOGOOD, M.D. Lond.,
Medical Superintendent of the Lewisham Infirmary.

Lewisham, Feb. 1st, 1902.

*** It was with a full knowledge of the existence of insane wards in workhouses and also of the treatment of patients in them that we advocated the system of "reception houses." The limited experience of those in charge of the "reception house in the shape of an up-to-date mental ward" at the Lewisham Infirmary is confirmatory of the principle laid down. But before the workhouse wards, where the people of unsound mind are detained prior to being sent to asylums, can be considered as fully equipped and suitable for a psychiatric clinic a great deal would have to be done, as anyone who is fully cognisant of the present system ought to know. Our correspondent's views as to the manner in which the public will estimate the receiving houses (we proposed the term "hospitals") are not in accordance with the views of those who have had larger experience, and his assertion that "any change would be for the worse" is merely the record of an opinion which ought to receive a rude shock. Dr. Toogood concludes his letter by flatly contradicting us, and on completely irrelevant grounds. If he had been familiar with the work and reports of the medical superintendents of asylums he would not have done so, that is, if he has any regard for the accuracy of what he writes.—ED. L.

## THE DOSE AND LENGTH OF INCUBATION IN MEASLES AND VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—The letter from Mr. Kingston Barton which appears in your issue of Feb. 1st, is so incoherent as to be difficult of understanding. A light, however, may be thrown on the latter half of it when we state that we declined absolutely to pay £5 that Mr. Kingston Barton demanded of us for want of success in vaccinations.

We are, Sirs, yours faithfully,
JENNER INSTITUTE FOR CALF LYMPH
(James Douglas, Manager).

Church-road, S.W., Feb. 4th, 1902.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*General Increase in the Plague Mortality.—Further Increase in the Famine.—The Rangoon General Hospital.—The New Director-General of the Indian Medical Service.*

THE plague figures for India have again risen. The total this week is 9566 deaths, as against 8005 for last week. They were distributed as follows: Bombay Presidency, 4307, as against 3814; Bombay city, 208, as against 168; Madras Presidency, 501, as against 418; Punjab, 2348, as against 2049; Bengal, 443, as against 316; Calcutta, 22, as against 28; North-West Provinces and Oudh, 665, as against 488; Mysore State, 791, as against 454; Hyderabad State, 49; Central India, 193; and Karachi city, 36. Poona city for some reason is left out, but I find from local reports that over 300 deaths occurred in it for the week ending Jan. 5th. Kashmir State had 193 deaths. It will be seen that the epidemic is now more widely distributed than ever and that in the majority of provinces it is increasing steadily. The recrudescence in Bombay city is unmistakeable and Poona city is in the throes of another severe outbreak There are also signs of development in Calcutta and the quarter of the city hitherto first affected is returning more cases. For the past year Karachi city records 3700 cases of plague, with 2984 deaths—a case-mortality of 80 per cent. For 1901 up to the end of November last the official returns for the whole of India give 307,000 seizures and 233,000 deaths, and up to Dec. 14th Bengal had 90,000 seizures and 73,000 deaths, as compared with figures of less than half these for the previous appearance of the patient; the peculiar transparent skin which one sees in phthisis was changed to a robust complexion. The bile-salts evidently play a very important part in the human economy, judging from the quantity manufactured daily and their absence in the excretions of the body. Physiologists tell us now that they play a subsidiary part in digestion. What, then, is their true function? My investigations satisfy me that they play an important part with regard to tuberculosis.

I am, Sirs, yours faithfully,
J. G. WILLIS,
Feb. 4th, 1902. Medical Officer of Health of Ilkeston.

## THE DANGERS OF A COMMON COLD.

*To the Editors of* THE LANCET.

SIRS,—I do not know if I am exceeding the bounds of your liberality in again venturing to write on the subject of colds. Rightly or wrongly, I consider it a question of supreme importance and I think you must admit that since I broached the question in THE LANCET of Nov. 9th, 1901, p. 1297, the correspondence has proved of much interest, and the points raised are not likely to be ignored by our profession. As to the general infectiveness of colds, the clinical evidence is only too apparent and any medical man can satisfy himself on this point if he will make careful and sufficient inquiries amongst his patients where colds have occurred. Personally, during the last three months I have kept a record of cases occurring in households where colds have been prevalent. So frequently have the majority of the family been affected more or less in the different households as to prove conclusively with what ease and rapidity the infection of colds is spread.

Amongst many instances I should like to mention the following. In a household of five adults, on Dec. 19th, 1901, the servant was taken ill—rhinitis, pharyngitis, slight bronchial catarrh, temperature never rising to 100° F. On the 22nd the lady of the house developed the same symptoms, temperature never rising above 99°. On the 23rd four visitors arrived at the house—viz., father, mother, and two children. On the 26th one of the children was taken ill with the same symptoms, temperature rising to 102°. The other child was taken ill on the 29th. On Jan. 2nd, 1902, the mother was taken ill, temperature not rising above 100°. On the 4th and 9th the head of the household and the second servant became infected. All the patients were practically convalescent in a week's time from the commencement of the illness. Similar examples occurred in a district some distance from the above. A mother and her elder daughter, a teacher in a school some miles from her home, came to see me. The mother was suffering from a subacute attack of bronchitis. She stated that her elder daughter had a cold; she caught it from her, and it brought on an attack of bronchitis, to which she was subject. Her younger daughter, who is the head-mistress at the same school, developed a cold on Dec. 30th, 1901. Here out of a household consisting of only four persons three suffered from cold. Upon further inquiry it appears that including the above two teachers seven are engaged at the same school, and without exception every one of them has suffered within a period of four weeks from colds. Only one was for a day or so prevented from her school duties, and none have found it necessary to consult a medical man. The symptoms generally complained of were slight nasal catarrh, headache, sore throat, hoarseness, slight cough, &c.

These cases must be considered either as febricula due to common cold or to a modified form of influenza. If this sequence of symptoms be looked upon as a common cold it must be considered as highly infectious and contagious. Regarding the question of influenza, I can only say from an experience of over 20 years in active general practice, firstly, they did not exhibit the symptoms of influenza, with the exception of its extraordinary infectiveness; and, secondly, that influenza was not prevalent in the district. Presuming that these cases, and others which in my opinion are clinically indistinguishable, and which go by the name of common colds, are influenza or a modification of it, it is evident that such an affection, which follows the trade routes and is only propagated by personal contact, cannot be too jealously isolated, and only carelessness would allow h a case to be in proximity to any person suffering from chronic disease of the respiratory tract In all probability and other domestic animals disseminate catarrhs and colds. In Gloucestershire and some other places popular feeling is such that if the domestic cat shows symptoms of a cold it is at once ostracised from the family circle. "Popular beliefs are not necessarily scientific fallacies." Injuries undoubtedly predispose the deposition of morbid products in the injured parts, as witness what is called a "collier's back" or say any fracture in rheumatic subjects. These cases become more prolonged, tedious, and painful owing to the presence of the secondary condition, rheumatism. Put as a proposition, it would read thus; Over-stimulation leads eventually to degeneration, and the form of degeneration depends upon the inherited and acquired characters of the individual. Further examples are shown in miner's nystagmus and trade palsies.

In a somewhat similar manner a vital or a chemical poison, such as is produced by colds in the system, is often the spark that lights up any latent mischief present. This is only a theory, but it is popularly accepted and requires to be proved or disproved. Its importance is self-evident. The essential thing to be inquired into is the bacteriology of colds. I am endeavouring to get this point worked out for myself, and it is in the hope that some of your readers, greater adepts in modern research than myself, may assist in this matter that I pen these lines.

I am, Sirs, yours faithfully,
Wigan, Jan. 21st, 1902. R. PROSSER WHITE.

## A POINT FOR PUBLIC VACCINATORS.

*To the Editors of* THE LANCET.

SIRS,—A short time back, on Jan. 2nd, lymph being urgently required, I sent a telegram to the National Vaccine Establishment and, knowing our applications for lymph by post were sent free to the same address, as O.H.M.S., I sent the telegram free as a test case. Two telegrams were sent in all. An application was made to me for payment which I refused, and I wrote a formal letter to the Post Office stating my reasons—viz., that my postal applications go free, as O.H.M.S., and that I did not see, therefore, why telegrams should not go in the same way. I inclose the application. When the objection was put forward by them that I was not an officer with a salary entirely voted for in Parliament, I pointed out that a policeman can report a case of swine fever by free telegram to the Local Government Board, as O.H.M.S., and that I thought that a public vaccinator, finding small-pox in two towns near his district, should be able to apply by free telegram in a similar way for lymph.

I consider the efforts of medical officers of health to stay small-pox, already scattered through many districts in England, ought to be helped as much as those of the policeman to prevent the spread of fever in a herd of swine. Though I am perfectly willing to pay the few pence for the telegrams I should like your opinion on the case, as the anomaly is so peculiar that the medical officer of health's applications must go by post as O.H.M.S., while the rural policeman can telegraph. I should like to hear how many public vaccinators received the same treatment that I have in their efforts to prevent a scourge from spreading. The Local Government Board agrees with the General Post Office in stopping its medical officers from obtaining supplies of lymph quickly by telegram at a time of necessity and apprehension in an infected district.

I am, Sirs, yours faithfully,
HENRY T. WHITLING, M.B., B.S. Durh.,
M.R.C.S. Eng., L.R.C.P. Lond.
Husband Bosworth, Rugby, Feb. 3rd, 1902.

[INCLOSURE.]

General Post Office, London, 1st February, 1902.

SIR,—With reference to your letter of the 8th ultimo, I am directed by the Postmaster General to inform you that the privilege of sending telegrams free of charge as on Government service is confined to officers of the Crown receiving salaries wholly provided for out of the annual Parliamentary votes.

The matter has been referred to the Local Government Board who state, in reply, that the position occupied by you does not entitle you to send telegrams free of charge.

In these circumstances I am to ask you to be so good as to affix stamps of the proper value to the inclosed forms, and to return them to this office.

I am, Sir, your obedient servant,
Dr. Whitling. C. G. HALL (for Secretary).

*** We agree with our correspondent that it is at least as important that a medical officer of health should be able to take, without expense to himself, immediate steps to arrest an epidemic of small-pox as that a policeman should be able

Committee in reference to the conscience clause of the Vaccination Act, 1898. A motion was proposed and seconded in the following terms:—

That it be recommended to the council that a petition be presented to Parliament praying for the repeal of Section 2 of the Vaccination Act, 1898, which exempts from penalty any parent or person who conscientiously believes that vaccination would be prejudicial to the child, on the ground that such exemption is a source of danger to the public health.

The motion was withdrawn on the understanding that Dr. Hope would submit to the next meeting of the committee his suggestions for the amendment of clauses of the Act. It is very satisfactory to note that in Liverpool revaccinations are very general and quite spontaneous.

Feb. 4th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *Newport and Monmouthshire Hospital.*

THE directors of the Newport and Monmouthshire Hospital have nearly always succeeded in providing a sufficient income to meet their expenditure, and in their report for the year 1901 they state that although it was at first feared that there would be an adverse balance of £165 the committee of the workmen's fund forwarded a contribution of £175, although over £1000 had been subscribed from the same source. If the Cardiff workmen were as generous as their fellows in Newport have shown themselves to be the finances of the Cardiff Infirmary would at once be placed upon a satisfactory footing. Indeed, the workmen's contributions in Newport compare very favourably with those in much larger towns such as Birmingham or Manchester. Although all the wards in the Newport Hospital are furnished only 56 of the 84 beds are at present in use, but when a sufficient income is assured the unoccupied wards will be utilised. Since the beginning of August when the new building was opened the visiting of patients at their own houses has been discontinued. At the annual meeting of the subscribers to the hospital held on Jan. 31st Mr. O. I. B. Mush, senior honorary surgeon, suggested that a railway ambulance should be kept in readiness to be sent to any part of the county, and £50 were at once subscribed towards its cost.

### *Prevention of Tuberculosis.*

The executive committee of the South Wales and Monmouthshire Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis has resolved to ask the local authorities within the area of the branch to adopt by-laws prohibiting, under a penalty, the practice of spitting upon the floors of public rooms and vehicles. The committee numbers among its members not only the town clerk of Cardiff but all the principal medical officers of health in the district; it is to be presumed therefore that such by-laws would not be *ultra vires*. A suggestion has been made that the convalescent home at Porthcawl, the only institution of the kind in South Wales, should be utilised all the year round for the treatment of cases of tuberculosis of the joints and spine.

### *Small-pox.*

Two cases of small-pox have been reported in Merthyr where there is excellent isolation accommodation, the district council possessing two hospitals in different parts of the town, and one of these with 34 beds is now being used exclusively for small-pox patients.—There are three cases of small-pox at Swansea, the patients being a man and two children.—A case has also occurred in the Hay Rural District on the borders of Brecknockshire. The patient in this instance was a young woman who had been visiting in London.—In the Herefordshire rural districts it has been decided to add chicken-pox to the scheduled list of notifiable diseases and to give public notice of the obligation resting upon householders to notify to the medical officer of health the existence of any case of infectious disease in their house.

### *Shepton Mallet District Hospital.*

The annual report of the Shepton Mallet District Hospital, which was established in 1869 and has accommodation for 20 patients, states that the expenditure during 1901 was £335 and that 110 out-patients and 112 in-patients were treated. The average stay in hospital of each in-patient was 19 days. It is evident therefore that the institution is worked economically.

### *Bristol Workhouses.*

Mr. R. H. Norgate, resident medical officer of the Stapleton Workhouse, reports that during 1901 there were treated in the infirmary or imbecile wards 664 patients, equal to 34 per cent. of the total number of persons admitted to the workhouse, and that there were 209 deaths. At the Eastville Workhouse, where Mr. I. C. Morgan is resident medical officer, there were 238 deaths during the year among the 740 patients admitted to the infirmary.

### *Cost of Asylum Patients.*

It has been found necessary recently to raise the charge made to boards of guardians for the care of pauper lunatics in the Herefordshire County Asylum to 12*s.* per head weekly. In 1896 the charge was 9*s.*, and the various boards of guardians in the county are very much exercised as to the cause of this increased cost. The Board of Guardians for Hereford, the largest union in the county, has had presented to it a statement giving the weekly cost of maintenance in 10 other asylums, from which it appears that at Worcester it is 7*s.* 7*d.* per head, at Abergavenny (Monmouthshire) 8*s.* 2*d.*, at Northampton 8*s.* 6*d.*, at Gloucester 8*s.* 8*d.*, at Oxford 8*s.* 9*d.*, at Somerset 9*s.* 4*d.*, at Salop 9*s.* 6*d.*, at Wiltshire 9*s.* 11*d.*, at Birmingham 10*s.*, and at Staffordshire 10*s.* 6*d.* In estimating the value of these figures for comparative purposes it must be borne in mind that only one asylum (Oxford) is of the same size as that at Hereford, where there is only accommodation for 600 patients, whereas in the asylums of Worcestershire, Monmouthshire, and Gloucestershire more than double this number of patients can be received. One cause of the increased cost at Hereford may possibly be put down to an outbreak of scarlet fever which recently occurred, involving the isolation of about a dozen attendants and several patients, and in connexion with which the asylum committee was not altogether free from blame in not having provided adequate isolation accommodation in spite of the repeated recommendations to do so by the medical superintendent (Mr. C. S. Morrison) and by the Commissioners in Lunacy.

### *Appointment of a Female House Surgeon.*

At the annual meeting of the subscribers of the Tiverton (Devon) Infirmary held on Jan. 29th the honorary secretary stated that Miss Elizabeth McIlney, M.B., Ch.B. Edin., had been appointed house surgeon. He added that in May, June, and October, 1900, and in January, 1901, the committee advertised for several weeks in the medical journals for a resident house surgeon at a salary of £80 per annum. In answer to the first advertisement no application was received, in answer to the second there was one—from a lady, in answer to the third there were three—all from ladies, and in answer to the fourth there were seven—four from gentlemen and three from ladies. The committee appointed each gentleman in turn and each either declined to take the appointment or agreed to do so and failed to carry out his agreement except the last, who arrived and was discharged on the following day. The committee having been without any house surgeon for some months eventually appointed a lady to the post.

### *Royal United Hospital, Bath.*

The annual meeting of the subscribers to this institution was held on Jan. 29th under the presidency of the Mayor of Bath. The medical report stated that 1239 in-patients had been admitted during 1901 as against 1384 in 1900. The out-patients numbered 7994, a decrease of 611 compared with the previous year. The financial statement showed that the total income amounted to £5670, including £1139 from workmen's contributions. Financially the year had been much better than its predecessors, but there still remained an adverse balance of £3374, although £1780 worth of stock had been sold out. The committee made an urgent appeal for more funds and added that unless the income was greatly augmented one of the wards would have to be closed.

Feb. 3rd.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The Morison Lectures.*

THE second Morison lecture of the present series was delivered by Dr. George A. Gibson on Jan. 22nd in the hall of the Royal College of Physicians of Edinburgh. The subject of the lecture was The Pathogeny and Pathology side, where the photograph was taken, are covered with houses. The six-inch ordnance map does not give the level of the precise spot where the destructor has been built, but close to it there is a level of 123 and another of 146 feet above the sea. Probably the destructor itself stands on ground about 135 feet above the sea level. Slightly to the north-east and not quite half a mile away there is a level on Windmill Hill put down at 300 feet, and somewhat nearer, but a little to the east, there is Daison Hill, which is also 300 feet high. Adding 150 feet for the height of the chimney to the level on which the destructor is built, the discharge of the fumes probably takes place at an altitude of 285 feet—that is, some 10 or 15 feet below the level of the hill plateaux behind, but to this the height of the trees may be added. To the north-west of the destructor the houses and villas near St. Mary's Church and the Roman Catholic church and convent are on altitudes set down in the ordnance map at 305 feet, 309 feet, and 300 feet above the sea level, and therefore they are all above the top of the destructor chimney. The villa districts to the south and south-west of the destructor, Shirburn-road, Thurlow-road, &c., are 200 feet above the sea level. To reach this district the wind must come over the hills shown in the illustration, by which it is deflected downwards, bringing the fumes straight upon the houses that are a little below the top of the chimney. The distance from the summit of the northerly to the southerly hills is considerably less than a mile and the destructor is built in the hollow about half way between the two ranges. It would be impossible to find a better site, if the object were to test the effects of destructor fumes when thrown direct upon inhabited dwellings. These fumes, I am informed, contain effluvia due to the presence of oils belonging to the paraffin group. These are probably produced by the breaking-up of animal and vegetable matter in the complicated series of action and reaction going on in the furnace. Impure paraffins were found in the flue of the destructor, and if imperfectly burnt they would occasion the smell described as that of a tallow candle. A dirty paraffin lamp burning oil of a very inferior quality would, technically speaking, have been a more correct description. The presence of carbonaceous matter in the dust would be due to the imperfect combustion of the oil. One analysis of the dust collected in the flue sets down the percentage of carbon at 12 80. The large quantities of silica, lime, iron, potash, &c., contained in this dust or grit would account for the irritation of the throat which has been the subject of so many complaints. It is to be hoped that the action of the baffling walls will reduce the prevalence of these symptoms. The placing of a destructor at the bottom of a basin, with houses built on the greater portion of the rim that surrounds the basin and the chimney barely reaching to the height of this rim, provides an excellent opportunity of testing whether the combustion is perfect and the fumes innocuous. So far it is safe to infer that this desirable result has not been attained As yet it is too soon to say whether the alterations recently made will prove that the destructor can be rendered absolutely perfect. In any case it is a risky experiment, but as it has been undertaken it is for those interested in the problem at issue not to miss such an unparalleled opportunity of studying under the most propitious circumstances this very important problem. The town of Torquay will have rendered great service in helping to decide the question, and those who have suffered during the course of these experiments will have at least the consolation of having contributed to solve a scientific problem in which all towns and large communities are deeply interested.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*The Royal Infirmary: Annual Meeting.*

AT the recent annual meeting of the friends of the Liverpool Royal Infirmary Sir William Banks announced that an important addition was in course of being made to the hospital. The new Royal Infirmary had now been in use for 11 years or more, and so soundly had it been constructed that it had not been found necessary to replace a brick or a beam. The committee at the time of building had been reproached with extravagance regarding the expensive manner in which the walls, floors, and ceilings of the wards had been constructed, inasmuch as they were impervious to all septic influences and beautiful to the eye. But in the end the policy of "thorough" had been justified. Nothing could exceed the healthiness of the building, while its cheerful interior made it a genuine pleasure to work in it. In one point only had it fallen behind. The whole structure and apparatus of surgical operating theatres had altered since the infirmary was built, and new apparatus for sterilising dressings and fluids had been introduced. The large theatre had been constructed on the best model of the day, some 11 years ago, but it had now become old-fashioned, even in that short space of time. A generous friend of the institution was now building, in place of that theatre, two new ones which would be equipped with the most recent improvements. These two theatres, with a small one now in use, would allow each surgeon a theatre for his own use—an advantage not possessed by many hospitals. The treasurer reported that the expenditure for the year was nearly £15,000, whilst the income was under £12,000. The hospital debt stood at £3612, or £780 more than in the previous year, and it would have been considerably larger but for the ex-lord mayor's century fund contribution. 353 more patients had received treatment than in 1900. One bed had been endowed in memory of the late Mr. James Harrison (a former member of the committee) by his family. There were now nine endowed beds in the hospital. Mr. Arthur Earle, the retiring president, announced his donation of 200 guineas to the charity. Two changes had taken place on the medical staff. Dr. T. R. Bradshaw had succeeded Dr. T. R. Glynn as honorary physician and Dr. R. J. M. Buchanan had become honorary assistant physician in Dr. Bradshaw's place.

*Unsatisfactory Sanitary Condition of the Infirmary for Children.*

The fiftieth annual report of the committee of the Liverpool Infirmary for Children deals with the unsatisfactory sanitary condition of the building. In spite of the care exercised by the medical staff and the prompt removal of any infectious case upon discovery, together with the temporary closing of some of the wards, still the hospital has not been free from outbreaks of scarlet fever and diphtheria during the year 1901. The general health of the staff also has been unsatisfactory. There has been much sickness among the nurses and serious cases of illness have occurred among the resident medical staff. The conclusions drawn from these regrettable occurrences by the committee and the medical staff were that nothing short of a new separate out-patient building and the entire rebuilding of the infirmary itself would enable them to carry on the work of the charity. They roughly estimated the cost of rebuilding at £50,000, and issued an appeal to the citizens for funds towards that object. The treasurer reports that £18,700 have already been promised in response to the appeal, which has enabled them to proceed with the erection of the new out-patient building opposite the infirmary in Mulberry-street. It is the unanimous opinion of all interested that the present site is the best possible fo[illegible] erection of a new hospital, being very central and abutting upon a large public recreation ground belonging to the corporation which can never be built upon, while in front there is a large open space. The site is high, with a good fall for drains, whilst the foundations are of sandstone. During the year there were 913 in-patients and 13,572 out-patients, involving 53,611 attendances.

*Small-pox in Liverpool.*

At the meeting of the Health Committee held on Jan. 23rd Dr. E. W. Hope, the medical officer of health, reported that there were 18 patients suffering from small-pox under treatment in the city hospitals. Most of them were cattlemen who had arrived from the United States. but they also included one person from London and another who had crossed Europe and had developed the disease after arrival in Liverpool. At the meeting of the Health Committee held on Jan. 30th Dr. Hope reported that eight cases had been notified during the week ending Jan. 25th, as against three cases in the previous week, and that 17 patients were under treatment in the city hospitals. No deaths had occurred. Three fresh cases were reported on Feb. 4th. The patients in these cases had been in contact with the batch of cattle-men who brought the disease into Liverpool a fortnight ago. As the new cases are traced to the original source the slight increase is not so alarming as if a fresh source of contamination had been discovered — A discussion took place at the last meeting of the Health

D.D. (Belfast), Professor Sinclair, M.D. (Belfast), and Mr. Edward Anning, M.A. (Dublin), have for the time no *locus standi* on the Senate, and there is now only one senator, the direct representative of the graduates (Dr. J. W. Browne). It is extremely unfortunate that this should have occurred at present, as on Saturday last (Feb. 1st) important matters relative to extern examiners came before the medical committee, of which Sir William Thomson and Professor Sinclair were members, and the further consideration of the subject is to be brought before the Senate on Feb. 7th.

### *Diphtheria at Howth and Baldoyle.*

At the last meeting of the North Dublin Rural District Council held on Jan. 29th the Local Government Board forwarded a report which they had received from Mr. D. Edgar Flinn, medical inspector, in reference to the continued prevalence of diphtheria in Howth and Baldoyle. It has been decided to close the schools in both of these districts and to adopt various other measures in order to insure the stamping out of the disease.

### *The Belfast Hospital for Sick Children.*

It was reported at the annual meeting of the Belfast Hospital for Sick Children, held on Jan. 31st, that during the year 1901 there were treated in the wards of the institution 684 children, an increase over the previous year of 111. Of these 404 were medical, 269 surgical, and 11 eye and ear cases. 28 deaths occurred—22 in the medical and six in the surgical ward. 272 operations were performed. In the out-patient department 5855 cases—3002 medical, 1153 surgical, 1071 eye and ear, and 629 dental—were treated. 187 children were received into the Convalescent Home. During the year Dr. R. Steen resigned his position as assistant physician, and Dr. R. M. Beatty was appointed in his place. A large class of senior students is as usual attending the hospital cliniques. The staff is most anxious, owing to the increase of intern patients—on many occasions children having had to be refused admission to the hospital, especially to the surgical ward, on account of every bed being filled—that the hospital should be enlarged by an addition being made to each of the wards, but the board of management has for the time being, owing to the state of the finances, thought it wiser to postpone the matter. The average expenditure per patient per day is 7½*d.* The total average cost per bed occupied is £44 10*s.*, which sum is inclusive of expenditure in the extern department. Greatly to the regret of the staff Dr. J. McCaw has been obliged, owing to pressure of work, to resign his position as secretary to the staff, a position which he has occupied to the entire satisfaction of his colleagues for the past 10 years, and Dr. R. R. L. Leathem has been appointed in his place.

### *Health of Belfast.*

From the report presented by the medical superintendent officer of health to the City Corporation of Belfast on Feb. 2nd at the monthly meeting it appears that Belfast is at present in a very healthy condition. Between Dec. 15th, 1901, and Jan. 18th, 1902, 242 cases of zymotic disease have been notified—viz., 69 cases of typhoid fever, 52 of simple continued fever, 41 of diphtheria, 38 of erysipelas, 21 of scarlet fever, 16 of membranous croup, and 5 of puerperal fever. In the five weeks ended Jan. 18th, 974 births were registered in Belfast and 688 deaths, making a natural increase of 286. There were 44 deaths from zymotic disease, 103 from phthisis, and 184 from diseases of the respiratory organs. The annual death-rate from all causes was 20·2, that for children under one year old 3·9, and that for those of 60 years and upwards 3·7 per 1000 of the population. The health of the city of Belfast shows a continued improvement, more especially in the number of cases of zymotic disease notified, as well as in the deaths therefrom, which have fallen from 2·5 for last month to 1·3 per 1000. The deaths from diphtheria and whooping-cough are fewer. So far no case of small-pox has yet appeared in Belfast, notwithstanding the very close and constant communication with various parts of England, where the disease is prevailing—London, Liverpool, &c.—as well as with Glasgow. The weather has of late been extremely cold, with a sharp, biting east wind.

Feb. 4th.

---

THE DRAINAGE OF TRURO.—At a meeting of the Truro Corporation, held on Jan. 20th, it was decided to submit to the Local Government Board a scheme for the drainage of the city, and to apply for sanction to borrow £21,000 for the purpose.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *The Predisposition to Tuberculosis.*

M. Albert Robin and M. Binet have shown upon previous occasions that 92 per cent. of patients suffering from pulmonary tuberculosis exhibit a very marked increase in their production of carbonic acid, and they now claim to be able to utilise this fact as a means to an early diagnosis of tuberculosis, and, moreover, to be able to say when a person is predisposed to infection by the bacillus of Koch. They communicated the results of their researches to the Academy of Medicine at the meeting held on Jan. 21st as follows. Among the descendants of tuberculous persons M. Robin noted in 60 per cent. of cases an increased consumption of oxygen which revealed the personal predisposition of the patients to tuberculosis. Instead of 5·5, the figure which represents the normal coefficient of the consumption of oxygen, the figure rose to 6·5, or 8 or even 10. In young people who were run down owing to excesses, or in those who were in a state of profound depression from various disappointments the coefficient was 8. In alcoholic patients the figure ran up even to above 10. M. Robin and M. Binet thought that they might apply these facts to therapeutics, and with the idea of discovering therapeutic agents capable of modifying the soil in which the tubercle bacillus would grow (they considered it impossible to act on the bacillus itself) they experimented with some 40 agents commonly used in tuberculosis with a view to investigate their powers as regards the fixation of oxygen in the tissues. For the present they have selected four, the efficacy of which has been known for some time. These agents administered to a healthy man have a remarkable effect in diminishing his power of fixing oxygen in his tissues. In a word, they retard tissue change and make the body into the exactly opposite condition to that which is most favourable for the growth of the tuberculosis bacillus. The therapeutic agents are cod-liver oil, arsenite of potassium, cacodylate of sodium (these two must only be used in normal doses, otherwise they increase tissue change), and rest in the horizontal position. Cold air is good provided that the body be kept warm; a heated air is bad, especially if the body be at the same time chilled. Life at high altitudes has a variable action according to the personal peculiarities of the patient, and the respiratory exchange ought to be studied in a patient at various altitudes in order to find that at which he does best. The same variations hold good for a marine climate. In the course of his observations M. Robin has seen young people in a very feeble and critical state in whom the respiratory coefficient had reached 8, but where by the use of rest and of cacodylate of sodium it came down to the normal figure of 5·5. A respiratory coefficient of 5·5 shows a condition of body inimical to the growth of the tuberculosis bacillus.

### *Fracture of the Forearm from Starting a Motor-car*

At the meeting of the Academy of Sciences held on Jan. 13th M. Sorel reported some cases of fracture of the forearm caused by starting a motor-car differing from those previously reported, which were cases of indirect fracture of the lower end of the radius by rupture of the anterior carpal ligament. In the case reported by M. Sorel there was a direct fracture at the junction of the lower and middle third of the radius owing to the blow of the crank handle on the external anterior face of the forearm, while at the same time the hand was forcibly extended. Contemporaneously the styloid process of the ulna was torn off. There was thus a direct fracture of the radial diaphysis and an indirect fracture of the lower ulnar epiphysis. There was no obvious deformity of the forearm as the shaft of the ulna, which was intact, served as a splint to the radius.

### *Obituary.*

Dr. Ballay, Governor-General of French West Africa, has just died from diabetes, a disease from which he had been suffering for some time past. He was born in 1847 and commenced professional life as assistant surgeon in the navy. In 1875 he went with Brazza to the Congo. It was this district which he described in his thesis for the doctorate.[1] He was made Chevalier of the Legion of Honour in 1879 and Officier in 1888. He lived in the Gaboon, the Congo, and finally in French Guinea until 1900. He then of Sensory Affections of the Heart." Under this head the lecturer described the afferent and efferent nerve connexions of the heart and the conditions which bring about the conduction of painful impressions from the heart to the nerve-centres, concluding with a description of the areas of referred pain in connexion with cardiac disease. The third and last lecture of the series was delivered on Jan. 24th, the subject being "The Therapeutics of Sensory Disorders of the Heart." In this lecture Dr. Gibson discussed the various measures and remedial agents which had at different periods been brought forward for the relief of cardiac pain. He showed that treatment was applied in two directions—(1) the alleviation of the paroxysm and (2) the prevention of its recurrence, both being determined by the nature of the underlying pathological condition.

---

[1] L'Ogooé, th. Paris, 1880, p. 43.

### *Edinburgh Royal Infirmary: Appointment of Pathologist.*

Owing to the appointment of Dr. D. A. Welsh as professor of pathology in Sydney, the post of superintendent pathologist to the Edinburgh Royal Infirmary fell vacant. The managers at their meeting on Feb. 3rd appointed Dr. Theodore Shennan, the senior assistant pathologist, to the vacant post. Dr. Shennan is a graduate of Edinburgh University and a Fellow of the Royal College of Surgeons of Edinburgh. He has been a teacher of pathology in the Edinburgh Extra-mural School for a number of years and at present holds that position in Surgeons' Hall. He formerly held the post of pathologist to Leith Hospital, and for a number of years he has acted as pathologist to the Royal Hospital for Sick Children. He is spoken of very favourably by those who have come most closely in contact with him in his work, and it is generally felt that the appointment ought to prove eminently satisfactory. Owing to the amount of time demanded of the superintendent pathologist in the discharge of his duties he resigns his post at the Children's Hospital and also his post as curator of the museum of the Royal College of Surgeons of Edinburgh. It is understood that the new superintendent pathologist will be allowed to do a limited amount of independent teaching in the extramural school.

### *Professor E. A. Schäfer on the Structure of the Liver.*

At a meeting of the Royal Society of Edinburgh held on Feb. 3rd Professor Schäfer of Edinburgh University read a paper on the Existence within the Liver-cells of Channels which can be Directly Injected from the Blood-vessels. He drew attention to papers written by Professor Browicz giving the results of observations on the liver-cells, in which he concluded that in addition to the presence of intracellular biliary excretory channels there were also special afferent nutritive channels in the liver-cells. Professor Schafer offered objective proof of this contention. He had found specimens in the Edinburgh University physiological laboratory of injected liver from the rabbit which clearly showed the intracellular nutritive canaliculi. On looking further into the matter he found specimens which had been left to the University by the late Professor Rutherford, some of which were apparently of this same rabbit's liver, while others purported to be from the liver of the cat. Some of these were labeled, "Shows injection within liver-cell," and one of them bore the date 1886. Professor Schäfer wrote to Professor E. W. W. Carlier of Birmingham, who at the date indicated was assistant to Professor Rutherford, to find out whether he could furnish any information with regard to the specimens. Professor Carlier wrote in reply that the specimens were injected by Simpson under his direction and used for class purposes, and that he had first noted the canals and had shown them to Professor Rutherford, who, however, would not allow him to publish a note of them. Whatever might have been Professor Rutherford's reason in so acting it was a matter for regret that the fact of the existence of intracellular canals in direct communication with blood-vessels should not have been made public. It was impossible to overlook the importance of the existence within the cells of any organ of vascular canals too narrow to admit blood corpuscles but doubtless capable of conveying the fluid portion of the blood directly to the cell protoplasm.

### *Small-pox in Glasgow.*

The number of patients in hospital in Glasgow is 48 During the last two days six new cases have been admitted and six patients have been discharged.

### *University College, Dundee.*

At a meeting of the Court of St. Andrews University on Feb. 2nd Principal J. Yule Mackay intimated that Sir W. Ogilvy Dalgleish had promised to contribute £5000 towards the completion of the conjoint medical school in Dundee, and the court unanimously resolved to express its appreciation of the great generosity which had prompted the donation and of the wisdom shown in the selection of the object to which it was to be applied. The plans for the new school have now been finally approved, and the work of building is to commence at an early date.—The following appointments to examinerships in the University of St. Andrews are announced:—Chemistry, Mr. H. Mackenzie, Jenner Institute of Medicine, London; physiology, Dr. William Snodgrass; pathology, Dr. T. Shennan.—Dr. W. Barrie Dow has been elected to represent the University at the Fourteenth International Congress of Medicine to be held at Madrid in April, 1903.

### *Aberdeen Sick Children's Hospital.*

One of the most interesting gifts presented to Miss Lumsden on the occasion of her retiring from the post of honorary superintendent of the Sick Children's Hospital is that from the past and present members of the medical staff. It consists of an antique bureau and on the desk is the inscription:—"Presented to Miss K. M. Lumsden, by past and present members of the medical staff of the Royal Aberdeen Hospital for Sick Children, on the occasion of her retiring from the post of honorary superintendent of the hospital after 16 years' service. 31st. Jan., 1901." The gift was accompanied by a signed letter of appreciation from all the members of the staff.

### *Aberdeen University Senatus.*

A meeting of the Senatus was held at King's College on Feb. 1st. It was intimated that the late Surgeon-General Robert Harvey, C.B., D.S.O., Director-General of the Indian Medical Service, who died at Simla in December, had bequeathed a legacy of £5000 to the University of Aberdeen, to be disposed of at the absolute discretion of the Senatus for the purposes of the University. The bequest, however, is not payable until the expiry of certain life interests.

Feb. 4th.

## IRELAND.

(From our own Correspondents.)

### *National Association for the Prevention of Tuberculosis.*

At the last meeting of the Executive Committee of the Dublin Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, held at the Royal College of Physicians of Ireland, Sir John W. Moore being in the chair, the honorary secretary was directed to draw the attention of the Public Health Committee to the fact that the system of voluntary notification of tuberculosis at present in force in Dublin has been found to be practically inoperative; that, moreover, the early recognition of the disease can only with certainty be effected by a microscopical examination from which the poorer classes of patients are now practically debarred; and that the remedy which has worked so successfully in New York and which has been adopted in nearly every important town in England and Scotland, as well as on the continent of Europe, should be put in practice here—viz., the establishment of a municipal bacteriological laboratory, not necessarily at any very great expense, where a competent bacteriologist could make the microscopical diagnosis of the specimens of sputum, &c., sent in by the dispensary medical officers and other medical practitioners who work among the poor. The information as to the presence or absence of the specific germ could be sent to the medical man within 24 hours free of all cost to the patient. There was a long discussion and other suggestions were offered to the Public Health Commitee.

### *Royal University of Ireland.*

As a result of some extraordinary mistake, or oversight, five of the senators of the Royal University elected by convocation to represent the graduates have become disfranchised. They were last elected on Jan. 17th, 1899, and they should have been apprised of the fact that their re-election must take place on Jan. 17th. No notice, was, however, taken of the matter, no arrangements were made, and, as a result, Sir William Thomson, M.D. (Dublin), His Honour Judge Shaw, LL.D. (Dublin), Rev. Professor Leston, there. So riotous did they now become that many were put under arrest and the others were ordered to disperse under threats of still stronger measures. On the following day protests were made by the students to the Ministers of Education and of the Interior but met with no sympathy. In consequence the disturbances were renewed and continued daily, with the result that the University was closed and its entrances were guarded by the police, bodies of whom were also stationed at the Institute of Anatomy and Pathology and at the Institute of Hygiene. In accordance with a peremptory order from the Minister of Public Instruction the University was again opened on Jan. 28th. In his letter to the rector, Professor Cerruti, Signor Nasi points out that the University cannot be closed for such a cause except for the purpose of depriving the students of the benefit of the examinations, and directs that, should the disorders be repeated within the University, the most stringent measures will be taken not only to restore order but to discover and to punish the delinquents. He adds that in future it is his intention to close the particular course of lectures in which such disorders may occur. So far there has been no renewal of the disturbances since the re-opening of the University. These frequently recurring students' riots at Rome and elsewhere are a source of much trouble and perplexity to the authorities as well as a vexatious interruption to the work of the schools, but they are regarded with considerable amusement, if not sympathy, by the populace and are not looked upon as really serious.

### *The Fourth International Congress of Obstetrics and Gynæcology.*

The International Obstetrical and Gynæcological Society having decided to hold its fourth meeting in Italy, and having entrusted the work of organising it to the Italian Obstetrical and Gynæcological Society, the latter has selected Rome as the seat of the Congress, which has been fixed for Sept. 15th to 20th next. The office of honorary president has been accepted by Baccelli and that of president-general by Pasquali. Morisani and Mangiagalli will preside over the obstetrical and gynæcological sections respectively, Pestalozza acting as general secretary. The following are the themes which have been selected for discussion: (1) the medical indications for the induction of labour; (2) hysterectomy in the treatment of puerperal infection; (3) tuberculosis of the genitals; and (4) the surgical treatment of uterine cancer.

### *Society for Succouring the Asphyxiated.*

This society, which was founded in 1880, has for its object the supervision of the Tiber within the city walls for the purpose of saving persons in peril of drowning and providing means for succouring those who in any other circumstances may be in danger of asphyxia. It supplies boats with expert boatmen, gives instruction by lectures and drill to the gendarmes of the Commune in the methods of restoring animation in cases of asphyxia, and offers rewards for acts of bravery done in attempts to save the drowning. In 1901 the society was instrumental in saving 44 lives, in some cases under circumstances so difficult that rewards were bestowed on several boatmen for the bravery they had displayed.

## CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

### *The late Dr. Spirido Mavrogeny Pasha.*

DR. SPIRIDO MAVROGENY PASHA, hakim bashi, or chief physician of the empire and chief physician to the Sultan, died in Constantinople on Jan. 22nd, at the age of 83 years. He belonged to one of the oldest families of Phanar, that suburb of Constantinople to which the Greek patriarchate was transferred after the Turkish conquest. He studied medicine at the University of Vienna, graduated there as M.D., and on his return to Constantinople was at once made physician to the Haidar Pasha Hospital, afterwards receiving an appointment as professor in the Imperial School of Medicine, a position which he held for 25 years. He was also very soon appointed physician to Hamid Effendi, at that time Prince Imperial, and now the reigning khalif or sultan. On the accession of this prince to the supreme power Dr. Mavrogeny still continued to be his medical attendant, and has therefore throughout the whole of his professional life been a court physician—a circumstance which prevented him from acquiring any considerable private practice. He had the rank of general, with a salary of about £T250 (£230 sterling). He was the general inspector of all the military hospitals, exercised control over all medical matters, and was the honorary president of the Imperial Medical Society of Constantinople. He possessed the full confidence of the Sultan and had the honour (which I do not think that any other medical man had) of being a *παρακοιμώμενος*—i.e., a man allowed to sleep in the vicinity of the Sultan's sleeping apartment. Dr. Mavrogeny was highly educated, being well versed in Greek and Latin literature and familiar with German, French, and English. He contributed both to general and medical literature. As an author he was well known under the pseudonym of "Hermit of Alem Dagh." Among his medical writings mention may be made of those on cholera, leprosy, and rabies. He also edited a medical magazine in Turkish and French, dealing principally with questions of public health. His personal reputation stood very high; he was greatly esteemed by all who knew him, the Sultan included, and most of the medical men in Constantinople were present at his funeral. The deceased possessed many Turkish and foreign Orders. He has left two sons, one of whom was the Ottoman Minister and Envoy Extraordinary at Washington a few years ago, and the other has been Ottoman Consul-General at Marseilles.

### *Plague.*

Cases of bubonic plague now and then make their appearance in Smyrna and Beirut, and the disease has also existed in Baghdad since last November. In the last-mentioned city it has been especially prevalent among the numerous Jewish population; the early cases being of a mild character and not terminating fatally were supposed to be malarial fever with enlargement of glands. An incident of the outbreak of plague in Constantinople was that differences of opinion arose between Professor Nicol and the municipal authorities. Although an expert bacteriologist, he was perhaps not of a very affable temper, and on finding that he was not a *persona grata* he handed in his resignation and went to Paris. Dr. Remlinger, who came to Constantinople as director of the Antirabic Institute, has been appointed director of the Bacteriological Institute in succession to Professor Nicol.

### *Public Health in Constantinople.*

Scarlet fever has been very prevalent here since last spring and according to the statistics published by the International Board of Health from 15 to 20 fatal cases are registered every week. There is no small-pox here at present. Very few sanitary improvements were carried out last year. Probably the most important was the draining of the Greek cemetery at Shishly, where, as indeed is the case throughout the whole of the peninsula on which Constantinople is built, the impermeability of the subsoil causes the rain water to be retained and greatly retards decomposition after interment.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

### *The Sixtieth Volume of the "New York Medical Record."*

THE *New York Medical Record* was founded in the year 1866, and the year just gone by witnessed the completion of its sixtieth volume. For the 35 years during which it has been in existence the paper has been under the charge of the editor who first launched it on the sea of journalism. There can be no doubt that the brisk rivalry between the various periodicals acts as an incentive to editors and publishers to produce publications which will excel, or at least successfully vie with, their contemporaries. It may be, perhaps, that the business aspect of the matter is too much considered, but the spirit of the times tends to commercialism even in medicine and it would be impossible to conduct a journal on purely altruistic principles. The *New York Medical Record* is an excellent type of a first-class American journal, and it worthily represents in other countries the best features of the school of journalism to which it belongs.

### *Manner of Action of the Nerves.*

Professor Loeb and Dr. Albert P. Mathews announced at the meeting of the American Physiological Society held in returned to France to rest there when the yellow fever broke out in Senegal and in the Soudan. The Government begged him to organise the necessary hygienic measures at St. Louis-du-Sénégal, and Dr. Ballay started at once. He died in West Africa esteemed by everybody. At the request of the Colonial Minister the Chamber of Deputies unanimously voted a sum of 15,000 francs for his funeral, and his obsequies were celebrated with great state.

Feb. 4th.

## SWITZERLAND.

(From our own Correspondent.)

### *The Operative Treatment of Tuberculosis of the Kidney.*

This formed the subject of an interesting lecture, accompanied by demonstrations on the part of Professor U. Krönlein, at a clinical meeting in Zürich on Jan. 29th. He referred to the first nephrectomy performed by Simon in 1869 in Heidelberg and to the great caution with which for nearly 15 years surgeons approached the region of renal surgery in general. His own experience of the last 20 years had been confined to 120 renal cases with 100 operations, including 50 nephrectomies; 42 of the patients who underwent the operation recovered and only eight succumbed. He gave the opinion of Professor Albert of Vienna, referred to in a manual on surgery in 1885, where the latter says: "I only mention nephrectomy in cases of renal tuberculosis in order to warn surgeons from performing such an operation, which in one case is said to have been successful." Professor Krönlein alluded to his own experiences, which showed a great prevalence of renal tuberculosis, as he had had 38 cases under his care—32 per cent. of all renal cases; 29 of these were operated upon. There were 24 nephrectomies performed, with two fatalities in very severe, acute, and desperate cases with high fever. 22 patients recovered, and in 17 cases a lapse of time of from seven months to ten years had passed since they were dismissed cured as regarded renal symptoms. This went to prove that tuberculosis first attacked only one kidney, and there was also sufficient evidence that the kidney was the primary organ affected among the different organs of the urinary tract (the genitals, the testes, the prostate, the bladder, and the urethra). Only in five cases out of the 38 referred to could no other tuberculous focus be detected clinically, though this did not exclude some hidden localisation of the tuberculous process; generally the lungs were affected. Yet the operation under strict indications was necessary and advisable in order to remove a dangerous tuberculous deposit from the body, even though in two of the nine cases not operated upon the patients ultimately recovered. The 38 cases were observed in patients between the ages of 11 and 50 years, with the following distribution as regarded age: 11 to 20 years, five cases; 21 to 30 years, 17 cases; 31 to 40 years, 11 cases; and 41 to 50 years, five cases. Of the patients 12 were males and 26 were females. The left kidney was diseased in 16 cases, the right kidney in 20 cases, and both kidneys were diseased in two cases.

### *Puerperal Eclampsia.*

At the same meeting Professor Th. Wyder, director of the Lying-in Hospital at Zürich, read a paper on Puerperal Eclampsia. He rejected the theory of infection and referred this alarming and dangerous disease to a partially uræmic, but often purely toxic, agency, the details of which remained still to be discovered. He laid stress on the desirability of examining the urine periodically in all cases of pregnancy, but more especially if symptoms such as headache, nausea, vomiting during the second half of pregnancy, involuntary movements, nervous excitability, loss of memory, &c., were present. This, he said, was of the utmost importance, as with due supervision and proper treatment the illness might be avoided or its dangers lessened. Prognostically much could not be said, as apparently slight cases might terminate fatally and very severe cases might recover. The mortality among mothers, which in pre-antiseptic days used to be 35 per cent., had been reduced to 20 per cent., and an investigation which Professor Wyder instituted, referring to 1100 cases, resulted in the same percentage. Stroganoff's statistics, with only six deaths in 113 cases, were worthy of record and consideration. Prophylactically the patient had to be put on a mild diet, ample excretion by the kidneys, skin, and bowels, had to be ensured, morphine was not to be used, but sometimes bromides might be employed. In actual eclampsia termination of the pregnancy at the earliest possible date was indicated, almost without regard for the infant's life which was in jeopardy owing to the severity of the toxic disease. Hospital supervision was most desirable. In cases of operative interference strictest asepsis must be ensured, hydrargyrum and carbolic solutions must be avoided for irrigation, and all heart toxins, such as chloroform, chloral, morphia, and veratrum, should be used in the smallest possible but still efficient doses. Protracted narcosis might do more harm than good. Stroganoff recommended small doses of morphia with enemata of chloral hydrate. Hot wet packs might prove very beneficial, whilst hot baths might be dangerous—and might induce cerebral hæmorrhage. In some cases venesection with consecutive rectal or hypodermic injections of saline solutions deserved attention, as did inhalation of pure oxygen.

Zurich, Jan. 31st.

## ROME.

(From our own Correspondent.)

### *Celebration of Professor Murri's Medical Jubilee.*

On Jan. 19th was celebrated at Bologna the professional jubilee of Professor Murri who for 26 years has taught clinical medicine in the university of that city. A large gathering of scientific men from all parts of Italy met to do him honour, many of the other universities, including Camerino, at which he graduated, sending special representatives to take part in the proceedings. These were opened by Professor Albertoni with an eulogistic speech in which Professor Murri's scientific work as well as his services as teacher and consultant, received very high and well-deserved praise. The distinguished Bolognese professor was then presented with his bust and a collection of his works in three handsome volumes. The latter contains many valuable contributions to medical literature, embracing an immense variety of subjects, contributions which were scattered through a great number of medical periodicals until thus brought together by his friends and admirers. Readers of The Lancet may remember two very able papers by Professor Murri which appeared in these columns some years ago. The first of these, "An Address on Experimental Craniotomy and Diagnosis of Cerebral Abscess,"[1] attracted considerable attention at the time. The other was upon the "Diagnosis of Tumour of the Cerebellum."[2]

### *Riots at the University of Rome.*

The return to his professorial duties at the Sapienza of the socialist deputy, Enrico Ferri, *libero docente* in Penal Law, who was lately expelled from the Chamber of Deputies for disobeying the ruling of the President, has given rise to some lively scenes amongst the University students. An unfortunate expression which escaped the irascible deputy during the recent debate on the state of Southern Italy had been greatly resented by the students hailing from that part of the kingdom and they determined to show their disapproval on the first opportunity. On the day of the opening lecture the municipal authorities, in anticipation of disorderly scenes, had posted a considerable force of police in the streets surrounding the University and had also kept a body of carbineers close at hand to be ready in case of any emergency. This did not prevent a large crowd from collecting, mostly composed of students, but to some extent also of working men, who were present to support the socialist students against those with monarchic sympathies. The appearance of Ferri on the scene was the signal for a general uproar and the two hostile sections from words speedily came to blows, using fists and sticks freely upon one another, but fortunately no more dangerous weapons. Surrounded by a cordon of police and a bodyguard of his sympathisers among the students Ferri with difficulty made his way to the lecture-room and there calmly proceeded with his lecture regardless of the tumult outside. The presence of the police in the precincts of the University was keenly resented by both sections of the students who claim a right of sanctuary within its walls and hold that the municipal authorities exercise no jurisdiction ooms were practically unventilated. He had asked hree times for certain necessary alterations in the sanitary arrangements, but without success. The general staff of attendants was sufficient in numbers, but not sufficiently rained. Working an asylum under the Public Service Board was not conducive to the best treatment of patients. Dr. McCreery, the inspector-general of asylums, corroborated his evidence and said that the principle of appointment by seniority adopted by the Public Service Board blocked the way of reform, and he had repeatedly reported that "the patients were not receiving the care and attention to which they were entitled." The asylum was overcrowded by 200 or 300 patients. The present arrangements were very unsatisfactory. The Board reported that the specific charges of neglect in the particular case for inquiry had not been substantiated, but that the relatives of the patient had grounds for preferring them, and in so doing had discharged a public duty, as they involved the larger question of the general management of the asylum, and it found the following to be conclusively proven:—

---

[1] The Lancet, Jan. 5th (p. 9), 12th (p. 79), 26th (p. 206), and Feb. 2nd (p. 267), 1895.

[2] The Lancet, Jan. 30th, 1897, p. 291.

> Pay patients are not kept separate from other patients, either in wards or yards. Paying and non paying patients alike do not receive he accommodation or treatment that is necessary. There is practically o attempt made to separate curable from incurable patients. The ards generally are overcrowded and so few in number that proper lassification and separation of patients are impossible. This is pecially the case on the male side, where for some reason two yards re, and have long been, kept empty. The wards and dormitories enerally are also overcrowded and are used in many cases for urposes for which they were not constructed or intended. The ospital wards are utterly unsuited for hospital purposes. Ventilaion generally, especially in the lower wards, is bad, chiefly owing to tructural defects. The equipment and appliances for curative purposes re little better than rudimentary. In the hospital sense of the term, here is no nursing staff. A large proportion of the attendants have not een specially selected or efficiently trained. The present indoor system f training has broken down and the proportion of probationers is xcessive. Bruises and abrasions of patients are numerous and estraint is relied upon to an extent that has long been discarded in English asylums. All promotion throughout the asylum is by seniority nd is in no way dependent on proven merit. The medical staff is underpaid and insufficient for the work that it has to perform. Its *ersonnel* is constantly changing. The result is that, as the inspector as reported, the purely medical treatment cannot be deemed satisactory. There is immediate need that the management of the asylum hould be withdrawn from the control of the Public Service Board and laced, as has been done in America with beneficial results, under he control of trustees or commissioners. There is immediate eed that the medical superintendent should be rendered upreme in authority and responsibility in his individual asylum. There is immediate need of the establishment of a pay asylum entirely eparate from any present public asylum. There is immediate need f the appointment of a large number of trained nurses, of an increase n the medical staff, and of additional equipment and appliances for urative purposes. There is immediate need of the withdrawal of the sylum from the control of the public works department, so far as lterations, construction, and sanitation are concerned, and of its being placed under some specially qualified and competent officer. It s only fair to add that the errors and defects which have been so prominently made public during the present inquiry have already been rought repeatedly under the notice of the department by the nspector of asylums and the official visitors in their official reports.

### *Hospital Affairs.*

The directors of the Sydney Hospital have decided to nake a very important alteration in the present system of eceiving patients. The practice for many years past has een to exact a payment (of 5*s.*, 10*s.*, and 15*s.*, but not xceeding £1 1*s.*, per week) from patients. Those who leclared their inability to pay anything were sent to the oard of health where they received a "pauper order" which dmitted them to the hospital and ensured the repayment to he hospital by the Government of the approximate cost of heir maintenance and treatment. The directors now propose o abolish all charges for patients and to make the instituion "a public hospital for the free medical and surgical reatment of the sick and necessitous poor, with or without ecommendation." The directors estimate that about £1600 per annum will be lost from the income of the hospital by his step, but boxes will be placed in each ward for voluntary contributions from patients and their friends, and, in order to prevent abuse, a stricter system of interrogation as o the financial position of applicants will be instituted. The reasons for the change are that many of the contributing patients conceive that they are paying full value for the ervices rendered and are not in receipt of charity, and that he officers of the hospital are their paid servants. On the ther hand, the really necessitous are put to unnecessary inonvenience and humiliation in having to obtain a Government pauper order. At the last meeting of the board of directors it was also reported that the Morcliff site of the eye departnent would probably be in possession of the hospital for nother five years, and the board thanked the ophthalmic urgeons for the trouble which they had taken in securing a suitable site.—The financial position of the Melbourne Hospital has recently formed the subject of an exhaustive report prepared for the *Argus* newspaper. It was found that the different Australian hospitals adopted such different systems of keeping their accounts that it was difficult to compare them. The total cost of maintenance per bed occupied was £74 11*s.* 5*d.* at the Melbourne Hospital, or £10 4*s.* 3*d.* above the average of all the leading Australian hospitals, the extra cost being on the items of provisions, alcohol, surgery and dispensary, and domestic expenses. The increased cost is ascribed to the more serious nature of the cases treated—especially the large number of infectious cases, and particularly diphtheria. It is recommended that the expenditure on infectious cases shall be kept in a separate account and that the expenditure on out-patients shall also be in a separate account from that on in-patients. The report says that the present income of the Melbourne Hospital is inadequate to enable it to carry on its duties as at present; that additional financial support is requisite, both from the Government and the public; and that the Government grant should never have been reduced as it was some years ago.

### *The Coast Hospital, New South Wales.*

The select committee appointed to inquire into the circumstances of the removal from the service of the late assistant storekeeper at the Coast Hospital, Sydney, has presented a report to the Legislative Assembly. It finds that the late assistant storekeeper was an energetic and painstaking officer and that he acted rightly in refusing to relax his scrutiny over the receipt of stores; that the action of the President of the Central Board of Health showed a carelessness or credulity almost incredible; and "that the admissions of the medical superintendent that the diet-sheets specify when two classes of goods are contracted for the low-grade foods are to be supplied to the patients and the high-grade to the staff, is a further proof of the incapacity of the President of the Board of Health to administer his department."

### *Sydney Dental School and Hospital*

The new dental school and hospital in connexion with the Sydney University was formally opened by Mrs. See, wife of the Premier of New South Wales. Professor Anderson Stuart explained the steps that had led up to the establishment of the school and the need for it, but said that the university was not anxious to continue it.

### *The Right of a Medical Man to Practise as a Chemist.*

On Dec 13th, 1901, Mr. Andrew Honman, was charged with carrying on business as a chemist, though not a registered chemist. It appeared that Mr Honman was one of the executors of the will of the late Mr. Blackett, a chemist, and in the capacity of executor he carried on the business, having as a partner a man who was a duly qualified chemist and who really conducted the business. Mr. Honman acted solely in the interests of Mrs. Blackett and her family. A great deal of correspondence had passed between the Pharmacy Board and Mr. Honman, and finally when the board threatened proceedings Mr Honman told the board to proceed, as he relied on his right as a Licentiate of the Society of Apothecaries to practise pharmacy. The case was dismissed, with 10 guineas costs against the board.

### *Victorian Trained Nurses' Association.*

The report of the council of the Victorian Trained Nurses' Association read at its first annual meeting showed that it was already a success, having 260 members. The association had been recognised by the Nurses' Association in Sydney and by the Government of New South Wales, so that members of the association were eligible for hospital appointments in that State. The financial statement showed a credit balance of over £100.

### *Broken Hill Medical Institute.*

At a meeting of the Broken Hill Friendly Societies' Council it was stated that the medical institute was not a success and would have to be closed. Owing to the opposition of the local medical men the committee had difficulty in securing suitable medical officers. This is another victory for the profession in the "Battle of the Clubs."

### *Obituary.*

Mr. F. W. Elsner, F.R.C.S. Irel., was found dead in his bed at Moru, New South Wales, where he had practised for the last week of December, 1901, at Chicago, that they had made an important discovery concerning the nature and manner of action of the human nerves. Both Professor Loeb and Dr. Matthews are attached to Chicago University and have been conducting investigations on the matter during the past summer. Electrical changes in the atoms of the bodily tissue, according to these gentlemen, are responsible for all the active phenomena of life, and these phenomena are not, as hitherto believed, due to food furnishing the tissues and muscles of the body with heat energy. Instead of food furnishing the muscles with heat energy the Chicago investigators declare that it supplies electrical energy, which, after being converted into mechanical energy, is responsible for all the muscular contraction and organic processes of living organisms. The foregoing, of course, is a mere outline and not an adequate description of the new theory, which it must be admitted is as yet only in a tentative stage.

### *The Carnegie National Institution of the United States.*

Mr. Carnegie's offer of $10,000,000 (£2,000,000) to found a national institution in Washington would now appear to have been accepted, although the form of the gift is only indicated as "5 per cent. bonds." An official announcement was made on Jan. 9th that the Board of Trustees had been incorporated under the terms of the gift Mr. Carnegie's purpose in requesting the various trustees to become members of the board is stated to be as follows :—

> It is proposed to found in the city of Washington, in the spirit of Washington, an institution which, with the coöperation of institutions now or hereafter established there or elsewhere, shall, in the broadest and most liberal manner, encourage investigation, research, and discovery, encourage the application of knowledge to the improvement of mankind, provide such buildings, laboratories, books, and apparatus as may be needed, and afford instruction of an advanced character to students whenever and wherever found, inside or outside of schools, properly qualified to profit thereby.

One of the prominent aims of this institution is to be the promotion of original research and to ensure the prompt publication and distribution of the results of scientific investigation. The fact that Dr. John S. Billings of New York, the well-known bacteriologist, has been appointed one of the trustees would seem to be a guarantee that medical and scientific research will receive due attention.

### *Award of the Gross Prize of $1000.*

The Philadelphia Academy of Surgery, as trustee of the Samuel D. Gross prize of 1000 dollars for original research in surgery, has awarded this prize, after six years' interval, to Dr. Robert H. M. Dawbarn of New York city. The treatise which won the competition was entitled "The Treatment of Certain Malignant Growths by Excision of both External Carotids." Upon this topic Dr. Dawbarn has worked as opportunity served for seven years past. The essay when published will contain the histories, with pathologist's report in each instance confirming diagnosis of malignancy, and specifying its variety, of 40 carotid extirpations by the author himself, and as many additional by about a dozen other surgeons. At least two of these are members of the Philadelphia Academy of Surgery. By the terms of Dr. Gross's bequest the prize essay must be published in book form and a copy thereof must be deposited in the Samuel D. Gross Library of the Philadelphia Academy of Surgery. Dr. Dawbarn was born in 1860 and graduated in 1881 from the College of Physicians and Surgeons in Philadelphia He is now Professor of Surgery in the New York Polyclinic College and visiting surgeon at the City and Polyclinic Hospitals.

### *Tetanus after Vaccination.*

According to the official report of the Board of Health of Camden, New Jersey, concerning 11 cases of tetanus after vaccination in that city, the investigation established the fact that all the virus used was free from tetanus, as shown by the State bacteriologist. Tests were made on rats by physicians from Cooper Hospital, and in none of those instances did tetanus, which was then acute, occur until three or four weeks after vaccination. During the past three months in Philadelphia from 700,000 to 800,000 persons have been vaccinated with the same kind of virus as was used in Camden and not a case of tetanus has occurred. The cases of this disease found prevalent are ascribed to a long period of dry weather with high winds and to a lack of proper care of their vaccination wounds on the part of the patients.

### *Deportation of Consumptives.*

A case has occurred to test the constitutionality of the Treasury ruling that consumptives shall be prevented from landing in this country as immigrants. A man and his family arrived in New York on Nov. 9th and friends met them and guaranteed that they should not become public charges. The authorities, however, refused to allow the man to land as, upon examination by the Marine Hospital physicians, he was found to be suffering from pulmonary tuberculosis. He was ordered to be deported, but a lawyer obtained a writ of *habeas corpus*, and the man is now in the Long Island Cottage Hospital in Brooklyn. The Act of Congress on which he is detained was intended to exclude idiots, insane persons, paupers, criminals, and persons suffering from a loathsome or dangerous contagious disease.—The New York Academy of Medicine has had under consideration the ruling of the Secretary of the Treasury in regard to tuberculous immigrants and has taken ground in opposition as follows : "The Academy of Medicine deeply deplores the decision of the Secretary of the Treasury which is not based either on clinical experience or on scientific experiments; and considers the exclusion of non-pauper immigrants and consumptive aliens visiting our shores unwise, inhuman, and contrary to the spirit of American justice. While the Academy upholds the fact of the communicability of tuberculosis and urges all possible precautions against the spread of the disease from the sputum and other tuberculous secretions, or from the ingestion of tuberculous food substances, it is opposed to all measures by which additional hardship is imposed upon the consumptive individual, his family, or his physician."

Jan. 24th.

---

## AUSTRALIA.

### (FROM OUR OWN CORRESPONDENT.)

### *The Plague.*

ANOTHER and fatal case of plague has occurred in Sydney. Rats have also increased in numbers and hundreds of them, killed in different parts of the metropolitan area, were found to be affected with plague. Both the Government and the municipal authorities have instituted a vigorous crusade against the rodents. The sewers have been flushed and fumigated and business premises have been disinfected. In the measures taken some delay occurred owing to divided authority ; some steps have to be taken by the Government and Board of Health, some by the municipal council, some by the Water and Sewerage Board, and some by the Harbour Trust. The Mayor of Sydney claims that he should be made responsible for concerting the necessary action, but surely the Board of Health ought to be the proper authority. In Brisbane another case of plague has occurred, and there and in all the States precautions against the spread of the disease, and especially by the destruction of rats, have been vigorously prosecuted

### *Infectious Diseases.*

New and stringent regulations regarding precautions against infectious diseases have been issued in New South Wales, especially as to the disinfection of houses, the sending of children to school, and the transport of patients.

### *Inquiry at Kew Asylum.*

Reference has frequently been made in these columns to the unsatisfactory condition of the hospitals for the insane in Victoria. A recent inquiry into a charge of alleged neglect of a paying patient at Kew Asylum has emphasised the urgent need for reform. The acting medical superintendent in his evidence before the Inquiry Board stated that he was practically in charge of 450 male and 415 female patients and a staff of 130 attendants, and had practically to attend personally to the whole of the male patients, having only a temporarily appointed junior medical officer to assist him. None of the nurses in the asylum were certificated and there had been no head nurse for 18 months. No nursing standard was required from the matron. Very little difference was made in the treatment of paying and non-paying patients, as the medical officers did not know whether they paid or not. Both classes when violent went to the same refractory ward. The superintendent said that he would like to alter many of the present arrangements, but to do so entailed alterations in the structure of the buildings. In one ward 23 patients slept and six had beds on the floor because there was no room for bedsteads. The single music was provided by Mr. Hahn, the well-known pianist, and by Mr. Harold Loch, violinist, and capital songs were given by Mr. Kendal Ward, Dr. Malcolm, Dr. Arthur W. Wilson, Dr. Watson, Mr. Baker, and Mr. Glenton-Kerr.

**Notification of Chicken-pox.**—At the meeting of the Radstock (Somerset) Urban Council held on Jan. 24th, at the suggestion of the medical officer of health it was decided to include chicken-pox in the list of notifiable diseases.

**Bequests to Hospitals.**—The late Mr. Henderson of Bodmin has bequeathed £1000 to the South Devon and East Cornwall Hospital, Plymouth.—By the will of Miss Joyce Jane Lunell of Chiculdale, Montpelier, Weston-super-Mare, £1000 are bequeathed to the Weston-super-Mare Hospital.

**Bristol Naturalists' Society.**—The annual meeting of this society was held on Jan. 23rd at University College, Bristol. After the business had been transacted Dr. A. B. Prowse, the re-elected president, read an interesting paper descriptive of Some Botanical Photo-micrographs of Common Objects. The meeting terminated with a hearty vote of thanks to Dr. Prowse for his services in the chair during the preceding year and also for his paper.

**Redruth Rural District.**—Dr. A. E. Permewan, the medical officer of health of Redruth (Cornwall) Rural District, in his annual report for 1901 states that 496 births (26·9 per 1000) and 331 deaths (18 per 1000) were registered. He makes a reference to an increase in the number of deaths from phthisis, several of them having occurred in miners who had returned from working boring machines in South Africa.

**Manchester Infirmary.**—At the meeting of the board of management of the Manchester Infirmary held on Jan. 27th the rebuilding of the infirmary on the present site was accepted as feasible, if some other than the pavilion plan were adopted. The committee of the board appointed to consider the matter had been instructed to obtain plans and estimates for a new hospital to be built on the present site. They are to be submitted to the board at an early date, and, if approved, a special meeting of the trustees is to be called to consider them. "They desired that a new hospital should be provided ...... upon the best principles and in every way worthy of Manchester, and in that desire they had, they were glad to say, the cordial sympathy of the medical staff." The committee further says that it cannot be done unless the trustees and the public generally subscribe largely. It remains to be seen whether this scheme will be warmly taken up or not. It is not beyond criticism.

**Banquet to Dr. W. T. Edwards of Cardiff.**—On Feb. 1st Dr. Edwards was entertained by his professional brethren in the town and district of Cardiff to a banquet in commemoration of the jubilee of his association with the medical staff of Cardiff Infirmary. The banquet was held in the Royal Hotel, Cardiff, under the chairmanship of Dr. W. Taylor, and there was a very large attendance. The Chairman, in proposing "Our Guest," said that Dr. Edwards was one of the original promoters of, and subscribers to, the University College of South Wales and Monmouthshire. In 1885, on the occasion of the visit of the British Medical Association, he was the president, and that Association was never better entertained anywhere than at Cardiff. They also, he added, considered their guest the founder of the Cardiff Medical School, of which he was a generous supporter. The toast was drunk with musical honours.

**The** annual dinner of the British Gynæcological Society took place on Wednesday evening, Jan. 29th, at the Café Monico, when there was a large gathering of Fellows and guests. The retiring President of the society, Dr. J. A. Mansell Moullin, presided, and among those present were Surgeon-General W. Taylor, C B., the Director-General of the Army Medical Department, Professor Clifford Allbutt, Mr. W. Watson Cheyne, C.B , Sir James Crichton-Browne, Sir T. J. Gallwey, K.C.M.G , C B , and Dr. Robert Barnes. Several ladies were present and the hearty reception of the toast of "The Ladies" showed the appreciation with which the Fellows acknowledged the innovation. The toast of "The British Gynæcological Society" was proposed by Sir J. Crichton-Browne in an amusing and witty speech and was responded to by the chairman The toast of "Our Honorary President" was proposed by Dr. H. Macnaughton-Jones and was responded to by Dr. Robert Barnes. Dr. W. H. Bourke kindly undertook the supervision of a successful musical programme.

**A Town Council Vaccinated.**—At the meeting of the Helston (Cornwall) Town Council held on Jan. 30th the mayor and all the members of the corporation decided that they would be revaccinated at once as an example to their townspeople, and that posters should be distributed about the town informing the public that they could be vaccinated or revaccinated free of charge.

**Compliment to a Medical Officer of Health.**—At the meeting of the Barnstaple Town Council held on Jan 27th it was unanimously decided to record the council's high appreciation of the admirable manner in which the late medical officer of health (Dr. Mark Jackson) had performed his duties and it was stated that through his insistency the Infectious Diseases Notification Act was adopted in Barnstaple.

**Revaccination at Swansea.**—At the meeting of the Swansea Board of Guardians held on Jan. 31st one of the public vaccinators reported that he could not cope with the large amount of persons who wished to be revaccinated at his residence. On Jan. 30th he revaccinated 170 people, and hundreds had to be turned away. The other public vaccinator reported in a similar sense. It was decided to open stations for revaccination, the hours being fixed to suit the working classes.

**South Devon and East Cornwall Hospital Clinical Laboratory**—The work in this laboratory from June, 1901, to January, 1902, included 155 examinations of clinical and post-mortem pathological specimens. Among these were examples of actinomycosis of the peritoneum, spleno-myelogenous leukæmia, forms of anæmia, the serum and sero-sedimentation diagnosis of enteric and undulant fevers, gonorrhœa, tuberculosis, diphtheria, blood counts, and hæmoglobin estimations. The histo-pathological work included specimens of some rarity—e.g., a duct cancer and a large-celled sarcoma with intra-cystic growths of the mamma, tuberculous pyosalpinx, lymphadenoma of the abdominal type, adenomyxoma of the parotid region, hydatid "membrane," an enormous diffuse pigmented "sarcoma" of the liver and varieties of sarcomata, epi- and endotheliomata, &c The number of histological, chemical, and bacteriological examinations made appears to testify to the utility of this department to the hospital.

**Presentations to Medical Practitioners.**—Mr. W. Black Jones, M.D., B.S. Lond., D.P.H., was on Jan. 17th presented with a framed engraving, "The Doctor," by the nursing class in connexion with the Beulah (Breconshire) Centre of the St. John Ambulance Association —On Dec. 26th, 1901, after dinner, on board the P. and O. steamer *Peninsular*, the chairman of the Sports Committee, on behalf of the passengers, presented the ship surgeon, Mr. A. W. D. Hunt, L.R.C.P. Lond., M R.C S Eng , with a silver paper-knife and bookmarker suitably inscribed, an ancient seal of Aryan design and Hindoo workmanship, and a silver matchbox, as a mark of respect and esteem.—On Jan. 18th, at Gunnislake, Cornwall, after the distribution of medallions and certificates to the successful candidates of the Gunnislake branch of the St. John Ambulance Association, the members of the class presented Mr Albert Bowhay, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H. Cantab , with a silver cigarette case as a mark of appreciation of his services as honorary lecturer.

**The Royal Institution.**—The Friday evening discourse at the Royal Institution on Jan. 31st was delivered by Professor A. Crum Brown, professor of chemistry in Edinburgh University, the title of his address being the Ions of Electrolysis He commenced with a reference to the polarisation of electrodes, a phenomenon which was for a long time unexplained but was at last shown by Schönbein to be due to the electrodes becoming covered with a thin film of the products of electrolysis. He then gave an outline of the gradual development of the theory of ionisation which originated with Faraday and was extended by Clausius, Hittorf, Kohlrausch, van't Hoff, Arrhenius, Principal Lodge, and others. According to the theory of ionisation, an electrolyte dissolved in water is dissociated into ions—a metallic chloride, for instance, being the last seven years. An inquest was held and the medical evidence was to the effect that the cause of death was heat apoplexy.—Mr. W. H. Tibbits, the oldest medical practitioner in the Western District of New South Wales, died at Dubbo recently. He had resided in that town since 1857, was connected with many of its public institutions, and was the oldest magistrate in the district.—Mr. T. L. Holthouse, who had practised in Ballarat, Victoria, for 40 years died on Dec. 9th, 1901. He was 82 years of age and was most highly esteemed. For 31 years he was medical officer to the Ballarat Benevolent Asylum.—Dr. Joseph Stapleton, of Wallsend, New South Wales, was found dead in the bush on Dec. 12th, 1901. He left home on horseback to go on a professional round and is supposed to have had an apoplectic attack. He was a native of Ireland, was 45 years old, and was unmarried. He was very charitable and popular, though somewhat eccentric.

Jan. 1st.

## Obituary.

### HENRY LANKESTER, M.R.C.S. ENG., L.S.A.

THE death took place on Jan. 30th, at his residence, Salisbury-road, Leicester, of Mr. Henry Lankester. The deceased gentleman, who was born in 1825, was a native of Poole, and went to Leicester in 1854. Subsequently he became a partner with the late Dr. Macaulay, and on that gentleman's death he started practice on his own account. For a considerable period he was surgeon to the Midland Railway Company for the Leicester and Rutland District, and he was held in the highest esteem by his professional brethren. In 1879 he became a member of the Leicester Town Council and in 1890 he was elected mayor of the borough, being in the same year raised to the aldermanic bench. In 1892 he was made a justice of the peace, and although on the extension of the borough boundaries he retired from the town council he nevertheless continued to take a deep and practical interest in local public affairs. He was President of the Leicestershire Band of Hope Union, a contributor to numerous agencies which had for their object the general well-being of the community, and, as a total abstainer, an ardent supporter of the temperance cause. Lately he had been in failing health and some few weeks ago he had a seizure, since when his recovery had been despaired of. The deceased married, in 1861, Miss Squire of Royston, Cambridge, by whom he had seven children—six sons and a daughter. The eldest son is physician to the Church Missionary Society. The funeral took place at the Leicester Cemetery on Feb. 3rd, amid many manifestations of the high esteem in which the deceased gentleman was held. The Mayor of Leicester and many members of the town council and other public bodies attended.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Axel Key, one of the most eminent of Swedish medical men. He was born in 1832 and after studying in Lund qualified in 1852. Later he went to Germany and worked under Max Schultze in Bonn and Virchow in Berlin. After his return to Sweden he was appointed to the chair of Pathological Anatomy in the Caroline Institute, Stockholm, and was the first editor of the well-known *Nordiskt Medicinskt Arkiv*. He published in conjunction with Dr. Retzius researches on the Structure of the Nervous System. He also worked at the pathology of the heart and was much interested in school hygiene. He retired from active work about five years ago.—Professor Luigi Chiminelli of the University of Rome.—Dr. Hugo Pernice, formerly Professor of Gynæcology in the University of Greifswald, a post which he held from 1858 to 1899. He was a native of Halle and studied medicine there, in Prague, and in Greifswald.—Dr. Destrée, Director of the Second Medical Clinic in Brussels, at the age of 43 years.—Dr. F. J. Soupart, formerly Professor of Clinical Surgery in the University of Ghent and Belgian Senator. His age was 91 years.—Dr. Bosdorff, Vice-President of the Berlin and Brandenburg Medical Society, at the age of 68 years.—Dr. Eduard Cramer, Extraordinary Professor of Hygiene in the University of Heidelberg. He was in his thirty-ninth year and was the son of Dr. Heinrich Cramer, Professor of Psychiatry in Marburg.—Dr. Louis Kagelmann of Hanover, at the age of 74 years. He was an active politician of the Social Democrat school.

## Medical News.

UNIVERSITY OF CAMBRIDGE.—At the congregation on Jan. 30th the following medical and surgical degrees were conferred:—

*M.B.*—A. H. Grey and A. C. Hudson, Trinity; R. G. Abercrombie, Caius; A. B. Dunne, Queen's; and A. P. Bowdler, Sidney.

*B.C.*—A. C. Hudson, A. B. Dunne, and A. P. Bowdler.

Dr. W. E. Dixon was admitted to the degree of M.A. *honoris causa*.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. Moritz Elsner, of the Infectious Diseases Institute, has been granted the title of Professor. Dr. Oskar Spitta has been recognised as *privat-docent* of Hygiene.—*Bonn*: Dr. M. zur Nedden has been recognised as *privat-docent* of Ophthalmology.—*Florence*: Dr. Gaetano Pieraccini has been recognised as *privat-docent* of Medical Pathology.—*Moscow*: Dr. Levshin is retiring from the chair of Clinical Surgery. His successor will be Dr. Zhakonoff, Professor of Operative Surgery. Dr. Krinkoff has been promoted to an Ordinary Professorship of Ophthalmology. Dr. Speranski has been recognised as *privat-docent* of Dermatology.—*Munich*: Dr. Martin Hahn, *privat-docent* of Hygiene, and Dr. Adolf Schmitt, *privat-docent* of Surgery, have been promoted to Extraordinary Professorships.—*Pisa*: Dr. Pinzani has been promoted to the Professorship of Clinical Midwifery.—*San Francisco*: Dr. L. Newmark has been appointed Professor of Neurology.—*Valencia*: Dr. J. Bartrina y Capella has been appointed Professor of Topographical Anatomy.—*Vienna*: Owing to the approaching retirement of Dr. Krafft-Ebing from the chair of Psychiatry several changes and promotions will take place. His successor will be Professo Wagner von Jauregg, Director of the First Psychiatric Clinic in Vienna. Dr. Anton will be brought to Vienna from Graz, Dr. Mayer, Professor at Innsbruck, supplying his chair, while Dr. von Sölder, now first assistant to Professor Krafft-Ebing, will migrate to Innsbruck to take charge of the psychiatric clinic there. Dr. Karl Kreibich has been recognised as *privat-docent* of Dermatology. A new bacteriological laboratory with an installation of the most modern description is to be erected in Professor Gruber's University Hygienic Institute. Dr. R. Kretz, *privat-docent* of Pathological Anatomy, has been promoted to an extraordinary professorship.

DEATH AFTER AN ILLEGAL OPERATION.—On Jan. 31st, at the Deptford Congregational Hall, an inquest was held on the body of a woman, aged 29 years, who died from blood-poisoning supposed to be due to an attempt by another woman to procure abortion. In the course of the evidence it was stated that the alleged abortionist had advised her victim not to call in a medical man, as it would get her (the abortionist) into trouble. If, however, she were compelled to call in medical assistance she was to say that her injuries had been caused by fighting with another woman. The coroner's jury returned a verdict of "Wilful murder" against the woman who performed the illegal operation.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—The President and Council of this society gave an enjoyable smoking concert and conversazione at the Great Northern Central Hospital recently. The out-patient hall, the use of which had been granted by the hospita committee, had been decorated with flags and flowers, an made an excellent reception-room. There was a larg attendance, amongst those present being Mr. N. Brand Baker, Mr. Fraser Black, J.P., Mr. Watson Surr, J.I Dr. Basil G Morison, Dr. G. de B. Watson, Dr. A. Wh field, Mr. Peyton T. B. Beale, Dr. Samuel E. Dore, Mr. Macready, Dr. Atkinson, Councillor Dr. W. A. Malcolm, Dr. Glover, Dr. J. Crabb, Mr. T. A. Cambridge, Mr. Mower White, Dr. Robinson, Dr. L. Freyberger, Dr. G. F. Blacker, Mr. T. H. Purvis, and Dr. Walsham. During the evening

the Medical Act are governed by the terms of that Act and the decisions thereunder, and the Secretary of State for the Home Department has no authority to interpret them As regards the last part of the question the subject of the sale of poisons is now being considered by a committee whose recommendations must be awaited before any decision as to the legislation suggested can be arrived at

### *The Spread of Small pox by Tramps*

Mr **PLATT-HIGGINS** asked the President of the Local Government Board whether he would state what steps the Local Government Board was taking to prevent the spread of small pox by tramps —Mr **GRANT LAWSON** Parliamentary Secretary to the Board, replied My right hon friend recently issued circular letters to boards of guardians in which he called attention to the risk of small pox being spread by means of casual paupers and pointed out the steps which should be taken by the guardians and their officers with a view of diminishing as far as possible the danger from this source

Mr **PLATT HIGGINS** asked if any consideration of expense such as extra remuneration to medical officers would be allowed to stand in the way —Mr **GRANT LAWSON** replied No it would not be allowed to stand in the way The board has not restricted expenditure in the combating of small pox in any direction

### *The Tuberculosis Commission*

Mr **CHANNING** asked the President of the Local Government Board whether he could state when the commission appointed to report on Professor Koch's theory that bovine and human tuberculosis were distinct diseases and incommunicable was expected to report —Mr **GRANT LAWSON** replied I am not in a position to state when the commission will be able to report but it is not likely that they can do so for a considerable time I am informed that very extensive experiments will have to be carried out by the commission and that for this purpose laboratories and other buildings have been erected on the farms where this part of the work is to be done It is, I understand impossible to say how long these experiments will take but arrangements have been made for the commission to occupy the farms for three years

### TUESDAY FEB 4TH

### *The Royal Army Medical Corps*

Sir **JOHN BATTY TUKE** asked the Secretary of State for War if an early opportunity could be given for debating the warrant for the reconstruction of the Royal Army Medical Corps which he had promised to present to the House —Mr **BRODRICK** replied: I am afraid that I am not yet in a position to say when it is probable that the vote for the Medical Establishment of the Army will be brought forward

Mr **BLACK** asked the Secretary of State for War whether with the view of encouraging graduates from the Scottish universities to enter the Army Medical Service he would appoint a professor from one of the Scottish universities upon the Army Medical Advisory Board as had been done in the case of the English and Irish universities —Mr **BRODRICK** replied: In selecting the members of the Board every care was taken to make it as representative as was consonant with the requirements of the Royal Army Medical Corps which necessitated the personal attention of members of the Advisory Board to the interests of the service Dr Galloway a distinguished Scotch graduate resident in London lecturer at Charing cross Hospital, and formerly an examiner in the faculty of medicine at Aberdeen University, was selected to represent the interests of Scotland I would however point out to the hon member that in addition to Dr Galloway three of the military medical members are graduates of Scotch medical schools and Scotland is therefore exceptionally represented on the Board —Mr **BLACK** Have any of these gentlemen any present connexion with a Scotch university?—Mr **BRODRICK** It will be impossible to make any alteration in the composition of the Board and I have not the least doubt that the interests of Scotland will be properly cared for

### *The Small pox Epidemic*

Mr **COGHILL** asked the President of the Local Government Board whether he could state the total number of cases of small pox in the metropolis since the present outbreak and whether it was the intention of the Government this session to bring in a Revaccination Bill in fulfilment of the pledge given by them in the session of 1898 —Mr **GRANT LAWSON** replied According to the Registrar General's weekly returns 2656 cases of small pox were notified in the metropolis between June 1st 1901 and Jan 25th 1902 With regard to the second part of the question I cannot hold out any expectation that the Government will introduce a Revaccination Bill during the present session I am not aware that any pledge was given in 1898 as to the introduction of such a Bill though the Government promised to consider the matter —Mr **COGHILL** Is not the cause of the present outbreak the invention of the "conscientious objector"—Mr **GRANT LAWSON** No, I think not

Sir **JOHN TUKE** asked the President of the Local Government Board if he would consider the expediency of adopting in connexion with the present outbreak of small pox in London the methods for procuring more general revaccination which were resorted to successfully in Glasgow in the year 1901 involving a house-to-house visitation of the community divided into manageable areas and the employment of all medical men willing to assist in the matter —Mr **GRANT LAWSON** replied: It would be impossible to adopt the Glasgow plan throughout the whole of London at one and the same time but my right hon friend has under consideration how far it might be practicable to adopt some such methods in particular areas

## Appointments.

*Successful applicants for Vacancies Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number*

**ALLARDICE WILLIAM C** M D C M Glasg has been appointed Assistant Surgeon to the North Staffordshire Infirmary and Eye Hospital.

dissociated into a metal (anion) and chlorine (kation). When an electric current passes the anions and kations are assumed to travel in opposite directions towards the kathode and anode respectively. To illustrate this migration of the ions Professor Crum Brown made an experiment in which solutions contained in a narrow U-tube were shown on the screen. A crimson column of potassium permanganate was interposed between colourless columns of (1) potassium nitrate solution and (2) potassium nitrate solution made dense with urea (a non-electrolyte). When an electric current was passed the crimson column moved slowly. Several other experiments were also shown.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### *Mr. Broadhurst's Vaccination Bill.*

THE Vaccination Bill introduced by Mr. Henry Broadhurst is a very simple measure. In one short enacting clause it proposes to abolish compulsory vaccination.

### *Vaccination Bill in the House of Lords.*

Lord Newton has introduced a Bill in the House of Lords to repeal the conscientious objectors clause in the Vaccination Act of 1898.

## HOUSE OF COMMONS.

### THURSDAY, JAN. 30TH.

#### *Tuberculosis in the Postal Service.*

Sir WALTER FOSTER asked the Secretary to the Treasury, as representing the Postmaster-General, whether the Postmaster-General had had his attention drawn to the report of the Association of British Postal Medical Officers on the prevalence of tubercle among postal employés and to the summary of preventive measures drawn up; and whether the Postmaster-General was prepared to adopt the measures therein set forth for the more effective prevention of tuberculosis among the staff of the Post Office.—Mr. AUSTEN CHAMBERLAIN replied: The Postmaster-General received the report referred to in due course. Some of the preventive measures suggested in it were already in operation and others that have been found practicable have been adopted. Statistics supplied by the Registrar-General show that the rate of mortality from phthisis and cognate diseases between the ages of 15 and 65 years is much greater in the country at large than amongst the established employés of the Post Office; and there is no reason to think that persons in the Post Office Service are more subject to these diseases than others.

#### *Vaccination Statistics.*

Mr. CORRIE GRANT asked the President of the Local Government Board whether he was aware that the Metropolitan Asylums Board had repeatedly declined to supply information as to the names and addresses, ages, and conditions as to vaccination of all small-pox patients treated in their hospitals, although they were required to give this information by Section 8 of the Vaccination Act, 1898, and whether children born in these hospitals and duly vaccinated and afterwards dying from small-pox were included in the statistical tables of the Metropolitan Asylums Board among unvaccinated cases.—Mr. LONG replied: The section mentioned by the hon. Member does not apply in the case of a small pox hospital maintained by the managers of the Metropolitan Asylums district, as the managers are not a sanitary authority within the meaning of the section. I am, however, informed by the managers that a register similar to that described in the section is, in fact, kept at the hospital ships, but that only two persons have made application to inspect it The reply of the managers to these applications, which, it appeared, were made on behalf of the National Anti-Vaccination League, was to the effect that arrangements would be made for the register being produced, assuming that the person wishing to inspect was prepared to comply with the regulations of the managers and to satisfy the medical officer before entering the ships that he was adequately protected against contracting small-pox. With regard to the last part of the question, it is the practice of the managers to classify as unvaccinated any person who was already infected with small-pox before vaccination was performed. I understand that no birth took place in the small-pox hospitals of the managers last year and that this year there have been only three births.

#### *The London Water Bill.*

Mr. LONG introduced at this sitting of the House the Bill of the Government for the establishment of a Water Board for the supply of water within London and certain adjoining districts and for the transference to this board of the undertakings of the metropolitan water companies. He explained that the Government had decided to take the sanitary authorities of "Water London" and to make it their duty to select representatives who would form the proposed Water Board. The sanitary authorities selected were the metropolitan boroughs and the City of London, the urban sanitary districts of the outside areas, the London County Council, and the county councils of the adjoining metropolitan counties. There were 28 metropolitan boroughs. Six of these—Islington, Kensington, Lambeth, St. Pancras, Stepney, and Westminster—would have two members on the body and the others one member each, the London County Council would have 10 members, the Common Council of the City of London would have two members, the Council of the Borough of West Ham two, the councils of East Ham, Leyton, and Walthamstow one each, the county councils of Kent, Middlesex, Surrey, and Hertfordshire one each, and the Conservancies of the Thames and the Lee one each. The outside urban districts would be grouped and each group would be represented by one member on the proposed board. There would be a total membership of 67, with in addition the chairman and deputy-chairman, who could be elected from outside the body and paid. These figures gave to London, as represented by the metropolitan boroughs, the City of London, and the London County Council, a majority of two-thirds of the representation on the new board. It would be the duty of the board to purchase the undertakings of the metropolitan water companies within an appointed time by agreement or, failing agreement, by arbitration. It was proposed to establish a special court of arbitration, consisting of Sir Edward Fry, late a Lord Justice of Appeal; Sir Hugh Owen, late permanent secretary to the Local Government Board; and Sir John Wolfe Barry, the well-known engineer. While the arbitration clause was an open one, giving full powers to the arbitrators, the Government had adopted the recommendation of the Royal Commission and had decided that in this case the usual addition of 10 per cent. for compulsory purchase should not be allowed. The Water Board would represent, control, and administer the whole area which was now governed by the eight metropolitan water companies and would issue stock bearing interest at 3 per cent. per annum.—In the debate which followed Mr. Long's introductory statement several members took exception to the limited representation given to the London County Council.

#### *Licensing Bill.*

A Bill was introduced by Mr. RITCHIE to amend the law relating to the sale of intoxicating liquors and to provide for the registration of clubs. Like the Bill of last session it endeavours to strike at habitual drunkenness. It gives husbands and wives protection against drunken spouses, provides for the committal of habitual drunkards to inebriate homes, and contains clauses which propose to make it an offence to supply drink to habitual drunkards. It also increases the powers of justices with regard to structural alterations in public-houses. With regard to clubs the Bill provides that they must all be registered and in certain circumstances be subjected to police supervision.

### FRIDAY, JAN. 31ST.

#### *The Charge for Vaccination Exemption Certificates.*

Mr. HARWOOD asked the Home Secretary whether there was any fixed charge for vaccination exemption certificates; whether he was aware that there was a variety in the scale of charges even in neighbouring towns; and whether he would endeavour to secure that these charges should nowhere be excessive.—Mr. RITCHIE replied: The charge for such a certificate varies in different districts in the same way as other fees chargeable by justices' clerks, though not to the same extent as some of these fees. I am doing my best to secure uniformity in respect of this fee as well as others, but my authority in this matter is contingent on a draft table of fees being submitted by the local authority.

### MONDAY, FEB. 3RD.

#### *The Case of Dr. R. Rendall of Great Yarmouth.*

Dr. MACNAMARA asked the Secretary of State for the Home Department whether his attention had been directed to the case of Dr. R. Rendall of Great Yarmouth, who on Nov. 28th, 1901, was summoned before the General Medical Council and deemed by that body to be guilty of infamous conduct in a professional respect on the ground that he held an appointment as medical officer for the Liverpool Victoria Legal Friendly Society, which canvassed for members, and which society had been established 60 years, was duly registered under the Friendly Societies Act, and comprised a membership of two and a half millions; and whether he would take the opinion of the law officers of the Crown with the view of ascertaining whether the General Medical Council had power under the Medical Acts to declare a properly qualified medical man holding such an appointment guilty of infamous conduct, and thus be able to erase his name from the Medical Register.—Mr. JESSE COLLINGS said: My right hon. friend desires me to say that he does not wish to enter into the details of the particular case referred to, as he understands that it is still, in a sense, *sub judice*; but he is advised that the powers of the General Medical Council as to deciding what is and what is not "infamous conduct in a professional respect" within the meaning of the Medical Act are clearly laid down by that Act and the decisions thereunder; and he sees no necessity for consulting the law officers of the Crown in the matter.

#### *The Sale of Scheduled Poisons.*

Mr. CALDWELL asked the Secretary of State for the Home Department whether he was aware that, under the law relating to the sale of scheduled poisons, an unqualified assistant of a medical man or of a registered chemist was prohibited from selling poisons, under penalty of a fine, but that no penalty was attached to the employer for any offence committed by such unqualified assistant; whether he was aware that in the case of registered medical practitioners the General Council of Medical Education and Registration of the United Kingdom had given notice that it would treat as infamous conduct in a professional respect, and have the names erased from the Medical Register, under the twenty-ninth section of the Medical Act, 1868, of any medical practitioners who might leave an unqualified assistant in charge of their medical hall or open shops, whilst no penalty was attached to the registered chemist who employed an unqualified assistant should that assistant sell scheduled poisons; whether it was within the power of the General Medical Council to declare the employment of an unqualified assistant to be infamous conduct of a professional respect under the Medical Acts; and, if so, whether he would introduce legislation which would equally punish a registered chemist who might similarly employ an unqualified assistant, seeing that the danger to the public is equally the same whether the unqualified assistant be that of a medical practitioner or of a registered chemist.—Mr. JESSE COLLINGS replied: My right hon. friend understands that under the Pharmacy Acts, 1868 and 1869, any person who, not being a chemist or a qualified medical practitioner, sells poison is liable to prosecution, but that there is no provision in those Acts for making the employer responsible for the acts of his apprentice or assistant except in the case of a breach of the regulations to be observed in the sale of poisons. As my right hon. friend has said in answer to another question, the powers of the General Medical Council as to deciding what is or what is not "infamous conduct in a professional respect" under

# Notes, Short Comments, and Answers to Correspondents.

## ANTISEPSIS IN HAIRDRESSING

LONDON, as in so many things is rather behind the times in matters of cleanliness as regards hairdressing In shaving possibly the chance of infection is not so great for although there is common use of the brush and soap to say nothing of the razor, yet hot water and soap are very fair bactericides in themselves But the common use of brushes and combs is not at all unlikely to be a fruitful source of infection People are wiser now than they were some 30 years ago when we knew a lady who on her children returning from school where they had had scarlet fever expressed her intention of taking them to a hairdresser so that their heads might have a good brushing Children's heads are always scurfy after scarlet fever and these machine brushes are so much better than an ordinary hair-brush said this artless person But apart from scarlet fever there are plenty of diseases likely to be spread by the use of common brushes and combs In Paris stringent rules are laid down for the sterilising of hairdressers implements In London however, it has been left to voluntary effort to establish a place where antisepsis is attended to The Antiseptic Hair Dressing Association has opened a shop at 51, Jermyn street S W where all the razors are fitted with detachable metal handles so that both blade and handle can be sterilised The combs are metal and so are the backs of the brushes Only hand brushes are used and for shaving each customer is given a separate dose of soap powder, taken straight from a little capsule The brush is sterilised after each using and the operators wear waterproofed sterilisable overalls The head rests on the chairs are pneumatic indiarubber pads which can easily be detached and washed All the basins are made with pedal taps We think that the idea is a very good one and deserves to succeed

## THE RELATION OF THE CHURCH TO SANITARY REFORM

THE vicar of the Church of St Michael and All Angels, Blackheath Park has sent us a copy of his *Parish Notes* for February We are glad to see that he refers to our recent article upon the Relation of the Church to Sanitary Reform and urges in the strongest manner the utility of vaccination The vicar quotes the figures recently published by the Metropolitan Asylums Board and adds 'We hope that no further argument is needed to induce everyone who reads and digests these figures to be revaccinated at once Argument is useless in dealing with pronounced anti vaccinationists Dr Johnson when a lady asked him why he had given a certain definition in his dictionary replied Ignorance madam sheer ignorance But the average anti vaccinationist is too ignorant to know that he does not know We hope that the clergy will continue to try to enlighten their flocks upon the subject of small pox and its preventive

## HOW DISEASE IS SPREAD

THE difficulties with which the sanitary authorities have to contend in their efforts to stamp out disease are enormous In a leading article in THE LANCET of Jan 25th (p 239) we referred to several cases in which persons suffering from infectious diseases had carried infection from place to place and we print below a further list of cases to which we have had our attention called during the month of January It should be remembered that in all probability the number of cases which receive the light of publicity bears but a small proportion to those which escape notice

At Warminster petty sessions on Jan 2nd a man was fined £1 and 8s costs for entering an inn whilst knowing himself to be suffering from small pox

At the East Kerrier District Council meeting held at Falmouth on Jan 4th the medical officer of health referring to scarlet fever which lingered about certain parts of his district, said that he had a strong suspicion that many cases were being concealed

The medical officer of the Llandilo-Talybont division of Llangyfelach Rural District Council told the following story at the meeting of the council on Jan 7th Four cases of typhoid fever were he said reported from the Fforestfach district, and these were due in the first place to infection imported from elsewhere A child died from typhoid fever in the Rhondda and the body was brought to Cockett for interment The funeral party, including the mother of the child visited two houses in the same street, one the house of the grandmother and the other the house of an aunt of the deceased child Exactly a fortnight later the mother of the deceased child died in the Rhondda from typhoid fever One case occurred in each of the two houses visited by the funeral party and the remaining two cases occurred in two houses which received milk from the grandmother of the deceased child, the milk being carried to these houses by one of the patients from the two houses already mentioned who was ailing for a considerable time before she kept her bed and before a medical man was called in A case of wilful exposure by a person *suffering* from scarlet fever was also reported A servant girl in Swansea was taken ill and although informed by the medical attendant of the necessity of avoiding exposure she proceeded to her home in Waunarlwydd

The following disgraceful case was disclosed at Barrow, Lancashire, on Jan 17th when a man was charged with neglecting his eight children whose ages ranged between three and 15 years The inspector for the National Society for the Prevention of Cruelty to Children said that the case had been under observation for over 12 months The children were found to be in a filthy condition and practically starving The house only contained five rooms yet there were no less than 23 persons living in it The man could earn at the steel works £5 a week, but he was always drinking and would not work The medical officer of health said that the house was in a deplorable condition The house came under his observation six months ago and it was there that the small pox epidemic broke out The family were all unvaccinated and owing to the outbreak of small pox in the house the disease spread to no less than 30 people in the town It might just as easily have spread to 30 000 Through these people it was carried to Staffordshire and Blackburn The authorities put new furniture and bedding into the house but these were soon in as filthy a condition as those destroyed The prisoner said that one of his elder girls aged 19 years went to Birmingham and that was how the disease was carried All this neglect he said, had occurred since his wife died He was sent to prison for four months

A married woman of West Town Dewsbury, was fined 20s and costs on Jan 21st for exposing a child suffering from scarlet fever, though warned of the infectious character of the disease

## THE CASE OF THE LATE MR R B ANDERSON

*To the Editors of* THE LANCET

SIRS —I shall be obliged if you will insert the following list of those who have been kind enough to respond to my appeal on behalf of the family of the late Mr R B Anderson As will have been seen from the announcement by the honorary secretary of the fund subscriptions will be received up to the end of February, so that there is still time for those who have been *thinking* of subscribing to do so The total sum received is still well under £200 a sum quite inadequate for the needs of the family While not wishing to make invidious comparisons I cannot resist pointing to the very different result of the Smyth appeal In that most deserving case money has simply poured in while here, in a case which ought to appeal specially and unmistakeably to the feelings of the profession and which could not be expected to get much help from the general public, repeated solicitations have only resulted in the beggarly sum before mentioned I should like to bring to the notice of the members of medical unions and ethical societies the example set by the Gateshead Medical Association At its annual dinner as the result of an appeal made by me the sum of £22 was raised without difficulty Could not this be done by other societies supposed to be interested specially in medical politics?

I am, Sirs, yours faithfully,

ALFRED COX

## THE DIAGNOSIS OF SMALL-POX

ON Feb 4th Dr John Colin Matheson of Gerrard street Soho —not of 11 Soho-square as stated in the Medical Directory,—appeared to an adjourned summons which charged him with neglecting to send a certificate to the medical officer of health that a patient under his care was suffering from small pox Dr Matheson elected to give evidence and said that on Dec 20th he was called to see a man named Thackery whom he found had a rash He was unable to form a definite opinion as to the nature of the disease and on the 21st the rash had extended all over the body The rash was

**CANE, HOWARD**, M.D., L.R.C.P. Lond., M.R.C.S., has been appointed by the London County Council Medical Officer to the Staff at the Crossness Outfall Works, vice Mr. J. Elliot.

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

**During the week marked copies of the following newspapers have been received:**—*Wynberg Times, Reading Mercury and Oxford Gazette, Western Morning News, Echo, Glasgow Evening News, Surrey Herald, Manchester Guardian, Morning Leader, Star, Leeds Herald, Manchester Dispatch, Daily Graphic, Evening Standard, South Wales Daily News, Standard, State, Freeman's Journal, Birmingham Post, South Wales Echo, Birmingham Mail, Hartlepool Mail, City Press, Tunbridge Wells Advertiser, Church Family Newspaper, Army and Navy Gazette, Clinical Journal, Nursing Record, Sanitary Record, The Rock, Nordiskt Medicinskt Arkiv, Revista Ibero-Americana de Ciencias Médicas, Wolverhampton and Coventry News, Middlesboro' Daily Gazette, &c.*

accompanied by subcutaneous hæmorrhages. He did not see Thackery again until the morning of the 23rd, when he suggested a consultation. The family, however, could not afford this, so he recommended Thackery's removal to the hospital. Thackery, however, died the same evening at home in witness's presence. The disease was diagnosed as hæmorrhagic small-pox. Witness denied that he ever told Miss Cookman that he had attended a case of small-pox or that he put his arm round her neck. Miss Cookman contracted small-pox. He allowed, in cross-examination, that he had given a certificate to Thackery that he was suffering from influenza. This was for a benefit society. Dr. J. W. Washbourn gave evidence on behalf of Dr. Matheson. He said that hæmorrhagic small-pox was difficult to diagnose. The symptoms presented by Thackery as described by Dr. Matheson were perfectly consistent with those of purpura hæmorrhagica. Mr. Fenwick said that the charge would be dismissed. There was no doubt that Thackery had died from small-pox, but there was a doubt as to whether Dr. Matheson knew that Thackery was suffering from small-pox. Dr. Washbourn remarked that in the present day the ordinary run of practitioners had very little chance of studying small-pox. He thought that the authorities of the small-pox hospitals ought to give opportunities to the general practitioner of studying that disease. With this remark we quite agree, and we also think that Dr. Matheson should have seen the patient on Dec. 22nd. All diseases accompanied by hæmorrhagic rashes are very serious, and surely it would have been possible to get a consultation at a reduced fee.

## VACCINATION FEES.

THE following report of proceedings at a recent meeting of the Hungerford Board of Guardians is taken from the *Newbury News*:—

> "*Vaccination.*—Statistics for the cost of vaccination for the last year were placed before the board. In 1898 the cost was £52 1*s.* 4*d.*; in 1899, £112 12*s.* 5*d.*; in 1900, £132 14*s.* 5*d.*; in 1901, £148 11*s.* 2*d.* The board considered the increase a very serious item and decided to support a petition on the proposition of Messrs. Brown and Clewett from the Edington Guardians to the Local Government Board, asking that the medical officers' fees might be reduced, as they did not consider it was the intention of Parliament that the Act should work out to such advantage to the medical officers."

The correspondent who sends us the cutting informs us that the scale for fees is as follows: for vaccination at the surgery, 2*s.* 6*d.*; for vaccination at a patient's house within one mile, 5*s.*; above one mile, 7*s.* 6*d.* He points out that by the new rules laid down by the Local Government Board the vaccinator has to attend every case until well. We have no information as to whether the fees mentioned were settled by the board of guardians in consultation with the medical men, or whether the decision on account of the two bodies interested was left in the hands of the Local Government Board; but, judging by the terms of the proposition of the Edington Guardians which was adopted, we suppose that the fees were fixed by the Local Government Board. We cannot see that the fees are excessive. A vaccinated patient wants looking after for a week at least and very often for 10 days or even longer. A small-pox epidemic is infinitely more expensive and if the guardians throw difficulties in the way of vaccination they may very probably find that the rates will be doubled or even trebled.

## A CURE FOR WARTS.

*To the Editors of* THE LANCET.

SIRS,—Would some of your readers kindly recommend a cure for warts (on the hands)? My patient—a lady—has been applying glacial acetic acid for months—I might say years—with absolutely no benefit. Indeed, in spite of this treatment some have actually increased in size, while fresh ones from time to time have made their appearance on the scene. All told, the number of these excrescences is over 15. Anticipating some comforting suggestions,

I am, Sirs, yours faithfully,
Feb. 3rd, 1902. AT MY WIT'S END.

## MEDICAL PRACTITIONERS AND THE SALE OF POISONS.

*To the Editors of* THE LANCET.

SIRS,—Your annotation in THE LANCET of Jan. 4th, p. 44, entitled, "Medical Practitioners and the Sale of Poisons," in reply to "Vulneratus," leads me to ask you a question as to my position (probably that of hundreds of others). For 20 odd years I have been in general practice and have dispensed my own medicine, either personally or through an assistant (not always qualified). Of course, numbers of such bottles of medicine have contained scheduled poisons. But I have never used a label containing my name and address, as I always have thought, and continue to think, that the addition of the name and address to the direction for taking the medicine savours of advertisement. With hundreds of others I use the ordinary surgeons' slip label, as it is called, but if the General Medical Council insists upon my advertising my name and address I must bow to its decision and do so. The further question of keeping a book falls in with the usual custom of keeping a copy of the prescription for future reference and not necessarily for registering the sale of a poison. As a matter of fact, I resent the idea of "selling medicine" altogether. I do not charge my patients for medicine: I charge them for treatment.

I am, Sirs, yours faithfully,
P. B. W.

*C. S. R.*—1 As the directors are paying the bill they would naturally expect to be able to choose the operator. If the workmen had made it a condition of their acquiescence in vaccination that they should be vaccinated by the surgeon to the works sick club the directors would probably have agreed. 2. We do not see from our correspondent's letter that the medical man in question knew anything of the works sick club, although he might have assumed that, in connexion with a business of such magnitude, such an institution was in existence. 3. We cannot guess what the "Royal College of Physicians" might think, but certainly the London College could find precedent for disapproval.

and Workshop Act, 1901.

# The Erasmus Wilson Lectures

ON

# THE GENERAL PATHOLOGY OF TUMOURS.

*Delivered before the Royal College of Surgeons of England on Feb. 10th, 12th, and 14th, 1902,*

By CHARLES POWELL WHITE, M.A.,
M.D Cantab., F.R.C.S. Eng.,
DEMONSTRATOR OF PATHOLOGY, THE YORKSHIRE COLLEGE, LEEDS.

## LECTURE I.

*Delivered on Feb. 10th.*

Mr. President and Gentlemen,—My first duty is to thank you for the honour that you have done me in appointing me to deliver this course of lectures and to express the hope that they will prove of interest to you.

In undertaking pathological research there are three methods that we can adopt: we can either consider the diseases of some particular region of the body, or we can consider separate branches of pathology, such as histology, bacteriology, pathological chemistry, or experimental pathology, or we can consider the different pathological processes which give rise to the phenomena of disease, collecting the necessary facts from different regions and by different means of research. The adoption of the first two methods without correlating the results by the third tends to produce a certain narrowness of mind which is not to the best interest of pathology. For instance, the bacteriologist tends to look upon the microbe as the be all and end all of disease, while the pathological chemist attempts to find the necessary factor in the many chemical products of metabolism. Those, also, who confine their attention to a particular region of the body tend to form ideas of pathology which are adapted to that region only. Now diseases are characterised by certain pathological processes, and these processes are essentially the same, whatever the organ or tissue involved. If we wish, then, to investigate any pathological process we must call to our aid all regions of the body and all methods of research. My own observations have been almost entirely histological. It is sometimes alleged that histology has said its last word in pathology, but this is by no means true. There still remains an immense field for research, more especially in the study of serial sections and in the minute cytological studies which have been up to the present time left mainly to the biologists.

The subject of these lectures—the general pathology of tumours—is one of surpassing interest both from the scientific and from the practical point of view; it is a subject which, in its broader aspects, has received little attention of late years, most recent work having been confined to the study of the malignant growths alone.

In the old days of humoral pathology tumours, like other conditions, were ascribed to the action of one of the so-called vicious humours; later, the blood, and then the lymph, was supposed to play the all-important part; then came the assumption of an hypothetical fluid ("blastema") from which tumours were supposed to separate out by a process akin to crystallisation. After Virchow had shown that every cell was derived from a pre-existing cell, the chief share in tumour causation was given to chronic irritation in spite of the fact that irritation might be prolonged for an indefinite time without giving rise to the development of a tumour Cohnheim and others attempted to find the common factor in the embryonic rudiment from which all tumours were supposed to originate, but they were obliged to exclude certain cases of undoubted tumour formation. Lastly, of late years, we have seen pathologists endeavouring to find a parasitic origin for sarcoma and carcinoma, although it is impossible, on this supposition, to explain the occurrence of congenital sarcomata. It is evident, then, that the common factor in the pathology of tumour formation has not yet been found, and it is with the idea of attempting to discover this common factor that I have been studying the pathology of tumour formation for the last four or five years. Early in my research it became evident that I could not limit myself to tumours alone, for they form part of a larger group of pathological conditions all of which have to be considered together. In these lectures, therefore, I propose to indicate the direction in which this common factor is to be looked for, and to do this I shall consider in order the classification, life-history, and causation of tumours.

### Classification.

Two methods have been adopted for the classification of tumours for pathological purposes; one based on embryology, the other on the histological structure. Now a classification based on embryology is unsatisfactory because an arbitrary period of development is chosen as the starting point—namely, that period in which the embryo consists of three layers, and yet, in spite of this threefold basis, tumours are divided into two primary classes only. It is also unscientific because, since a large portion, at least, of the epithelium of the genito-urinary tract is derived from the mesoblast, it is possible for any kind of epithelial tumour to arise from any one of the three layers. We should, therefore, have epithelial tumours occurring in both of the primary classes and, in consequence, from an examination of any particular tumour, it would be impossible to decide in which class it should be placed. Those who have adopted this method have never carried it out completely; they have assumed that, contrary to the generally accepted views of embryologists, epithelium does not arise from the mesoblast, and they include in the mesoblastic group such tumours as the neuromata and gliomata, which are epiblastic in origin. We can, therefore, conclude that an embryological system of classification is of no use at all. A classification based on histology is not open to these objections; the basis—namely, the histological structure—being a well-defined one, we can, by an examination of any particular tumour, readily determine to which class it belongs.

Having decided, then, that the classification is to be founded on a histological basis, we have next to consider the method by which the different classes can be best formed. The method of which I shall make use is substantially the same as that which I published about three years ago.[1] The ultimate morphological elements of which the organism is composed are the *cells*. It is unfortunate that we have no satisfactory terminology to express the various kinds of cells, but have to make use of such cumbersome expressions as "connective tissue cells," &c. I would suggest that, following the precedent set by the terms "leucocyte," "phagocyte," &c., we should make use of the termination *cyte* to express the meaning *cell*, so that we should have the terms "fibrocyte," "chondrocyte," &c. Epithelial cells might be called "epicytes" and a general term for the connective tissue cells would be found in the term "desmocyte." We should thus have a uniform system of cellular terminology. The cells immediately resulting from the cleavage of the ovum are *indifferent cells*—that is, the individual cells have no characteristics which distinguish them from each other, and in the course of development similar cells may give rise to very different structures. As development proceeds the cells become differentiated into two great classes: (1) cells which in the course of proliferation remain in contact with each other, covering surfaces and lining tubes—namely, epithelial (including endothelial) cells; and (2) cells which in the course of multiplication become separated by intercellular substance or by connective tissue, such as the connective tissue cells, muscle cells, and nerve cells. These last might be collectively named "mesocytes." Now in order that the cells may fulfil their proper functions they are arranged in a definite and orderly manner. These arrangements of cells are called "*tissues*" and are of two kinds: (1) special tissues which have special functions to perform, and (2) connective tissues which act as supports to the special tissues. Again, in order that the tissues may properly perform their functions they are arranged among themselves so as to form *organs*. The organs are, in their turn, so arranged as to form the organism.

Starting from this threefold basis we arrive at a simple and satisfactory classification of tumours. Firstly, taking them in the reverse order, we have a class of organ tumours or organomata. In these tumours we can recognise distinct organs or parts of organs which, however, are not arranged so as to form a body or part of a body. The best known example of this class is the dermoid cyst, in which can be recognised skin, teeth, bones, &c., which are arranged

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

**Agent for the Advertisement Department in France—J. ASTIER 8, Rue Traversière, Asnières, Paris.**

blood-vessels and connective tissue, every tumour would have a compound name. Compound names should be restricted to (1) tumours compounded of two or more species of the same genus, and (2) tumours compounded of the species of corresponding genera of the histiomata and cytomata. Thus we can speak of myxlipoma, osteochondroma, fibrosarcoma, &c., and we can also use the term "adenopapilloma." In other cases, if it is necessary to qualify the species it should be accomplished by using a qualifying adjective We should thus speak of a fibrous adenoma or a vascular fibroma, &c.

With regard to the term "cancer" I would enter a plea for restoring to it the old meaning, as signifying any kind of malignant growth. As a synonym for carcinoma the term "cancer" is redundant and useless, whereas it would be of great use as synonymous with the more cumbrous term "malignant disease."

## CLASSIFICATION OF TUMOURS.

### *A. Organomata or Organ Tumours.*

Teratoma (dermoid cyst).

### *B. Histiomata or Tissue Tumours.*

(*a*) *Connective tissue tumours* (*desmomata*).—Fibrous tissue, fibroma; fat, lipoma; mucous tissue, myxoma; notochordal tissue, chordoma (of Ribbert); cartilage, chondroma; bone, osteoma; and neuroglia, glioma.

(*b*) *Lymphoid tissue tumours* (*lymphomata*).—Lymphadenoid tissue, lymphadenoma (lymphoma); and bone marrow, myeloma.

(*c*) *Muscle tumours* (*myomata*).—Smooth muscle, leiomyoma; and striated muscle, rhabdomyoma.

(*d*) *Nerve-tissue tumours* (*neuromata*).—Medullated nerve-tissue, myelinic neuroma; and non-medullated nerve-tissue, amyelinic neuroma.

(*e*) *Epithelial tissue tumours* (*epitheliomata*).—Squamous epithelium, squamous adenoma and squamous papilloma; columnar epithelium, columnar adenoma and columnar papilloma; spheroidal epithelium, spheroidal adenoma; and endothelium, angeioma and endothelial papilloma.

### *C. Cytomata of Cell Tumours.*

(*a*) *Tumours of indifferent cells* (*blastomata*).

(*b*) *Tumours of connective tissue cells, also of lymphoid tissue cells and muscle cells* (*sarcomata*).—(1) Pure sarcomata: round cells, round-celled sarcoma; spindle cells, spindle-celled sarcoma; and giant cells, giant-celled sarcoma. (2) Compound sarcomata: fibrous tissue cells, fibro-sarcoma; cartilage cells, chondro-sarcoma, &c.

(*c*) *Tumours of epithelial cells* (*carcinomata*).—Squamous cells, squamous carcinoma; columnar cells, columnar carcinoma; spheroidal cells, spheroidal carcinoma; and endothelial cells, endothelial carcinoma.

From this scheme of classification we arrive at the definition of a tumour: a tumour is a mass of cells, tissues, or organs, resembling those normally present in the body, but arranged atypically, which grows at the expense of the body without at the same time subserving any useful purpose therein. It will be seen that the distinguishing peculiarity of tumours is that they are atypical, not in the structure, but in the arrangement of their component parts.

Having thus classified tumours by analytical methods let us now apply the opposite method of synthesis—that is, let us consider what other pathological processes are allied to tumour formation. Firstly, there are certain cases of progressive hypertrophy of organs which resemble tumours in many respects Examples are to be found in the prostate, the breast, the spleen, the thyroid gland (goitre), the bones (leontiasis ossea), and possibly also in the lymphatic glands (Hodgkin's disease). In the next place there are certain cases where the whole of one tissue, usually the connective tissue, of an organ undergoes progressive hypertrophy. This is met with in the progressive fibrosis of nerves, in the prostate, where either the epithelium or the stroma may undergo a progressive increase, and possibly also in some cases of cirrhosis of the liver. Again, there are cases of progressive hyperergia or progressive increase of functional activity, such as is found in the kidneys (in diabetes insipidus), in the leucocyte-forming organs (in leucocythæmia), perhaps also in the thyroid gland (in Graves's disease). It is also found in many nervous and mental diseases and in diseases of metabolism. Lastly, there are cases of progressive metaplasia as, for example, in myositis ossificans. All these processes resemble tumour formation in the progressive character of their course and in the fact that they cannot be ascribed to definite extrinsic causal agents and, with tumour formation, they may collectively be called the "progressive processes."

Bearing in mind the foregoing scheme of classification, we can draw the following conclusions. 1. Every kind of tissue in the body has its representative tissue tumour. 2. Every kind of cell, with the exception of nerve-cells, has its representative cell tumour. Cell tumours of nerve-cells have not been described, but muscle cells are represented by myosarcoma, cartilage cells by chondro-sarcoma, and the different kinds of epithelial cells by the different kinds of carcinoma, &c. 3 Tumour formation is not an isolated process, but must be considered in its relation with other closely allied processes.

## RUDIMENT OF ORIGIN.

I propose now to consider the life-history of tumours and shall commence by discussing the rudiments from which they arise.

Cohnheim[5] endeavoured to find the essential factor in tumour formation in the rudiments from which tumours take origin. According to him all tumours originate in rudiments composed of embryonic cells, separated in the early stages of development, which retain their embryonic characters for an indefinite period of time. It will be unnecessary for me to discuss this theory fully because no one, I imagine, at the present day believes that such a rudiment is a necessary antecedent to tumour formation. It will suffice to point out that this theory will not explain the occurrence of a tumour in a scar or chronic ulcer. Cohnheim himself recognised this difficulty and attempted to evade it by saying that these growths were not tumours in the proper sense of the word. Senn[6] endeavoured to surmount this difficulty by supposing that the rudiment of embryonic cells might be derived by proliferation from adult tissues. These rudiments of Cohnheim, with the exception of moles, have never been described and some of those which have been adduced in support of this theory do not fulfil the conditions laid down by Cohnheim.

Although tumours do not in all cases arise from embryonic rudiments there can be no doubt that they do so in some cases. It is well known that tumours may arise in moles which may be regarded as examples of these rudiments, and the theory would seem to be especially applicable to those tumours which I have called blastomata. In many cases, especially in papillomata and carcinomata, the tumour may be seen to rise directly in the normal tissues at the seat of origin. Some observers state that when this is the case they do not arise from the fully formed cells of the tissue but from the proliferative or mother cells. Undoubtedly tumours are more common in those tissues which exhibit the greatest proliferative capacity, or, in other words, in those tissues which display the greatest capacity for regeneration such as epithelium and connective tissue, but I see no difficulty in supposing that the adult cells, provided that they have not undergone any degenerative change, may undergo proliferation and thus give rise to a tumour. Cells which are in active division naturally assume a more elementary or, as it is called, embryonic condition, but to say, as some do, that before they can proliferate they must undergo a reversion to a more embryonic state is, in many cases at least, I think, to put the cart before the horse.

Tumours may also take origin in the tissues of a pre-existing tumour or in inflammatory products. Thus a carcinoma may arise in an adenoma, a sarcoma in a myoma or in the granulation tissue of a scar or ulcer.

Since the different forms of connective tissue are mutually convertible by the process known as metaplasia, it is not always necessary to presuppose a rudiment consisting of the same kind of tissue as that of which the tumour is composed. For example, since cartilage can arise in fibrous tissue, as is seen in drill bones, it is not necessary to suppose a cartilaginous rudiment to explain the origin of a chondroma. The size of the rudiment, or area of origin, of a tumour is variable; in some cases it may involve the whole of an organ, while in others it may be very minute and it may conceivably consist of a single cell. With regard to the rudiment, then, we can draw the following conclusions. 1. The rudiment may consist (*a*) of a sequestrated collection of embryonic cells, such as described by Cohnheim; (*b*) of the tissues normally present at the point of origin; and (*c*) of tissues of new formation, either of inflammatory origin or indiscriminately. Secondly, we have a class of tissue tumours or histiomata in which we can recognise distinct tissues which, however, are not arranged among themselves so as to form organs. A fibroma, for example, is a mass of fibrous tissue which is not arranged so as to form a tendon or fascia. Each of the tissues of the body has its representative tumour in this class. Lastly, we have a class of tumours which can be called cell tumours or cytomata, in which we can recognise the cells which, however, are not arranged, at any rate in their growing portions, so as to form tissues. In this class we have carcinomata derived from epithelial and endothelial cells and sarcomata from connective tissue (and muscle) cells. We also have certain tumours which do not fall under the heading either of "sarcoma" or of "carcinoma"; they have been called by various names such as "adenosarcoma," "sarcoma carcinomatodes," &c., and they have sometimes been called "teratomata," thus confusing them with such tumours as dermoid cysts, &c. As I propose to form a new genus for these tumours, I must justify myself by giving a description of their histological characters. These tumours are most frequently met with in the genito-urinary tract, especially in the kidney where they are usually congenital, they are also found in the parotid region and in the liver and I have seen a case in the roof of the naso-pharynx. As met with in the kidney these tumours are seen to be composed mainly of round cells resembling those of a round-celled sarcoma; these cells may be called the primary cells of the tumour. Imbedded in this sarcoma-like tissue are a number of epithelial tubes which may be simple in form or irregular and branched. In some places these tubes may form cysts which may contain intra-cystic growths. In other places may be found spindle cells and striated muscle fibres; fat and mucous tissue may also be present. On more minute examination the epithelial tubes are seen not to be sharply marked off from the sarcoma-like tissue, but the cells of the tubes pass imperceptibly into the surrounding cells. If serial sections are made the tubes are found not to be connected together but to lie completely isolated among the primary cells. The other tissues present also shade off gradually into the surrounding cells. The tubes can be seen to arise by a circular grouping of the primary cells. At first this group has in its centre a mass of homogeneous material apparently derived from the cell bodies; later this material disappears, leaving a central lumen in the group of cells which have now taken on epithelial characters. In some cases the tubes are occupied by a mass of flattened epithelial cells resembling squamous cells. Some of the tubes undergo further changes by the ingrowing of the wall on one side so as to make the lumen assume a crescentic shape on section. When this is the case the epithelium on the outer concave border of the crescent becomes flattened so as to resemble endothelium, the epithelium covering the ingrowth retaining its cubical form. The whole resembles exactly an embryonic Malpighian body with its capsule of Bowman and glomerular tuft before the capillaries have entered it. The explanation of these appearances is to be found as follows. The primary cells of the tumour are to be regarded as indifferent cells derived from the intermediate cell-mass of the embryo; these cells, as they proliferate, undergo differentiation, some forming epithelium, others muscular fibres and other structures which may be present. In fact, just as sarcoma is a tumour of connective tissue cells and carcinoma of epithelial cells, so these tumours are tumours of indifferent cells; and just as in sarcoma some of the cells may form definite connective tissue of different kinds, and as in carcinoma some may form epithelial tubes, so in these tumours some of the cells may undergo differentiation and form epithelium and the other kinds of tissue that are met with. Similar appearances are seen in some parotid tumours. In these growths the primary cells are often irregular in shape and have numerous protoplasmic bridges connecting the adjacent cells with each other, resembling the prickle cells of squamous epithelium. If different parts of the tumour are examined it is found that, on the one hand, the cells become separated and the protoplasmic bridges lengthened by the interposition of a homogeneous intercellular substance, thus forming typical mucous tissue or cartilage; while, on the other hand, by a closer apposition of the cells they come in contact and form epithelial tubes which at first contain, as in the kidney tumour, a homogeneous substance which subsequently disappears. These tubes are, as in the former case, isolated among the primary cells of the tumour. Other observers have held the same views as regards these kidney tumours. Mr. F. T. Paul in 1886[2] was of the opinion that they grow out of a developmental abnormality while the tissues of the embryo are still in an imperfect state of differentiation; and Mr. Keith W. Monsarrat[3] states that they are traceable to a perversion of the cellular elements from which, under normal development, the Malpighian bodies and convoluted tubules should arise. Mr. Monsarrat is of the opinion that the sarcoma-like cells arise by proliferation from the epithelial tubes, but he does not give any reason why the cells should be derived from the tubes rather than the tubes from the cells as I have stated above. The fact that the tubes lie isolated in the midst of the sarcoma-like cells points to the view that they are of secondary formation. From these facts it is evident that these tumours are neither sarcomata nor carcinomata, and we are therefore justified in allotting them a distinct place in our classification. I propose for these tumours of indifferent cells the name of "blastomata," which name was, I think, first proposed by Dr. Herbert Snow in a somewhat similar sense.[4]

---

[5] Lectures on General Pathology.

[6] Pathology and Surgical Treatment of Tumours 1895.

It would appear to be impossible to distinguish between undifferentiated cells and some forms of connective tissue cells. In fact, it is possible that the round cells of a round-celled sarcoma in reality correspond to these undifferentiated cells and that this growth is, therefore, a pure blastoma, but it is not worth while, on this account, to alter the name of this growth, since it would not serve any useful purpose and would only lead to confusion. The criterion, therefore, between a blastoma and a sarcoma is the fact that in the former some of the cells become differentiated into epithelial cells.

Although the characteristic of the cytomata is the fact that the cells are not arranged so as to form tissues, yet, in many cases, this is only true of their growing portions. In the older parts of the growth fully-formed tissues may be present. In columnar-celled carcinoma, for instance, we find well-formed epithelial tubes, and in sarcoma it is not uncommon to find fully-formed fibrous tissue, cartilage, or bone, and we have seen that in the blastomata differentiation and the formation of distinct tissues occur. The formed tissues are, however, of secondary development and not primary as in the histiomata.

In drawing up a tabular classification of tumours it must be remembered that the species and genera are not so well defined as in a classification in biology, hybrid tumours being frequently met with. If the different kinds of connective tissue tumours are regarded as species the different kinds of epithelial tumours must also be so regarded, so that if fibroma and chondroma are species, carcinoma, sarcoma, and myoma are genera. Under the term "teratoma" I should include only those tumours in which distinct organs, or parts of organs, without any regular arrangement, can be recognised. The term should not be used of a growth merely because it contains a variety of tissues, nor should it be applied to supernumerary limbs and other malformations. The tissue tumours are named by appending the suffix *oma* to a root which expresses the tissue which constitutes the essential part of the growth. Following this rule, the generic name for epithelial histiomata should be "epithelioma." This term has, however, unfortunately been applied to the corresponding cell tumours in which place it is redundant and wholly unnecessary. In consequence we have no generic or specific term for these growths, "adenoma" and "papilloma" being names given to varieties of the species of the genus epithelioma. I should include under the term "adenoma" any tumour which has as its characteristic feature tubes or spaces lined with epithelium whether or not it arises in connexion with a gland. Adenomata sometimes take origin from a surface epithelium as in the skin, in which case they are formed of tubes lined with squamous epithelium, and in the bladder when the tubes are lined with transitional epithelium. The fact that a tumour is composed of epithelial tubes does not necessarily imply that it arises from tubular structures. The term "neuroma" should be confined to those tumours which contain nerve-cells as well as nerve-fibres.

As regards compound terms in the nomenclature of tumours, I am of the opinion that they should be used according to some definite rule. The mere presence of different tissues in the same tumour is no ground for giving it a compound name, otherwise, since all tumours contain of diffuse sarcoma of the liver. Growth is both central and peripheral, and there is often a secondary formation of definite tissues such as fibrous tissue or cartilage. I have already considered the growth of the blastomata.

### TERMINATION.

Tumours in most cases continue to increase in size without attaining to any final termination. In some cases a limit is reached owing to a change in structure such as ossification or calcification. In other cases, again, a tumour after growing for a time may become stationary. In rare cases a tumour may decrease in size and ultimately disappear, and this without undergoing ulceration or necrosis. Sir William H. Bennett, in a clinical lecture at St. George's Hospital about three years ago,[9] gave examples occurring in his practice which show the possibility of malignant growths completely disappearing without any special treatment. In four cases verified microscopically as sarcoma the patients regained perfect health, the tumours disappearing completely. One of these was an abdominal spindle-celled sarcoma, two were melanotic sarcomata with disseminated growths, and the other was a sarcoma of the testis. In two cases of carcinoma in which the primary growth was removed and in which recurrence took place the recurrent growths subsequently became smaller and eventually almost completely disappeared. In one of these cases the primary growth was in the testis and in the other it was in the breast, and both were verified microscopically. Another case of carcinoma of the breast (not verified) was known to have remained stationary for 15 years. Another was a case of malignant disease of the pylorus with obstruction; this was not verified, but at the operation for gastro-jejunostomy numerous secondary growths in the omentum and under the liver were seen and handled. In this case the patient recovered completely and was well five years after the operation, no growths being then discoverable. He also mentions a case of apparently malignant disease of the cervical glands too extensive for operation in which the patient recovered. Besides these remarkable cases—and they were only examples of many more which had come under the observation of Sir William Bennett—there have been recorded lately many cases of carcinoma of the breast which have improved after the operation of oöphorectomy in combination with thyroid feeding and other cases which have improved without special treatment. It is, therefore, a mistake to say that a tumour always continues to grow without limit; it may, under certain conditions which are imperfectly understood, become stationary or even diminish in size or disappear completely.

### PHYSIOLOGICAL CHARACTERS.

We have next to consider whether the cells and tissues of which a tumour is composed are capable of behaving physiologically like the cells and tissues of normal organs, or, in other words, are the cells and tissues of a tumour capable of performing any function? In considering this question we have to remember the fact that the cells of a tumour are in a state of more or less rapid proliferation and we should not, therefore, expect to find them very active in the performance of any function. Moreover, owing to the atypical arrangement which is characteristic of a tumour, there is no mechanism by which the performance of a function can be initiated, and, for the same reason, any function that may be performed is incapable of being utilised. The muscle-cells of a myoma, for instance, are probably capable of contraction, but, owing to the want of nervous connexion and the atypical arrangement, this power of contraction is not manifested and, if it did take place, it would serve no useful purpose. In spite of this there are several facts which show that the cells of a tumour are capable of functionating. The sebaceous glands of a dermoid secrete sebum, the cells of an adenoma or carcinoma of the intestine secrete mucin, adenomata of the thyroid contain colloid, and adenomata of the breast sometimes contain a milky fluid. Also the cells of a squamous-celled carcinoma undergo keratinisation, those of a carcinoma of the stomach form pepsin and rennin, and those of a carcinoma of the pancreas contain all the ferments proper to the pancreas, and this is true, at any rate in the case of the pancreas, of secondary, as well as of primary, growths (Waring).[10]

Perhaps the most remarkable physiological characteristic of tumour-cells is the property which they possess of storing enormous quantities of glycogen. In this respect, according to Brault,[11] they far exceed all the normal cells of the body and they can only be compared with the rapidly proliferating cells of the embryo. Those tumours which grow the most rapidly contain the greatest amount of glycogen, and from the study of the amount contained in a tumour the rate of growth can be judged. The cells of carcinomata and sarcomata are loaded with glycogen, while the surrounding tissues show a complete absence of it. The presence of this glycogen raises some interesting points for our consideration. Firstly, what is the meaning of this great store of carbohydrate material? Carbohydrate material is the great source of energy in the living organism; it is to the body what the fuel is to the steam engine. In the case of the embryo and in tumour formation energy is manifested by the multiplication of cells, and in order to supply this energy the cells store up carbohydrate in the form of glycogen. Secondly, what is the origin of the glycogen? Presumably it is formed in the same way as under normal conditions from the circulating glucose; if, however, the supply be deficient, it can be derived from the proteids of the body as in the severer forms of diabetes. Lastly, what becomes of the glycogen? Although there is such an enormous store of glycogen, yet, as far as I know, malignant disease is seldom or never accompanied by glycosuria. The glycogen is used up in the multiplication of cells because the central parts of a carcinoma, where proliferation has ceased, are completely free from it. It is probably directly oxidised and eliminated as carbon dioxide and water. This question of the presence of glycogen in tumours is well worth further study, especially by those who take a special interest in metabolic processes.

### PATHOLOGICAL CHANGES.

The pathological changes to which tumours are subject need not detain us since they are the same to which any normal tissue is liable. Tumours are liable to the various retrogressive processes, especially to mucoid and fatty changes and calcification, to necrosis, to inflammation and repair, and to the formation of new tumours.

### CLINICAL CHARACTERS.

It will be noticed that in the classification which I have given the histiomata and cytomata correspond respectively to the simple and malignant tumours of a clinical classification. Most authors state that tumours, usually simple, may occasionally take on malignant characters, and this is especially supposed to be the case with chondromata. This idea is based chiefly on a case reported by Paget of a chondroma of the testis which gave rise to metastatic growths in the lungs and elsewhere. This case, however, was re-investigated by Kanthack and Pigg,[12] who found that it was not a pure chondroma, but that it contained carcinomatous elements, and in the same way it will, I think, be found that whenever a tumour that is apparently a tissue tumour displays malignant properties it is in reality a cell tumour.

In my opinion the difference between simple and malignant tumours is to be found in the manner in which they grow. The growing area of a cell tumour consists of cells, either separate or in small groups, not forming any definite tissue, any formed tissues that may be present in the tumour being of secondary formation. The tissues in a tissue tumour, on the other hand, are of primary formation. For example, the growing area of a columnar-celled carcinoma consists of columnar cells in rows or groups which only secondarily give rise to epithelial tubes, whereas in an adenoma the growing area consists of epithelial tubes similar to those in the older parts of the tumour. Similarly in a chondro-sarcoma the growing area consists of collections of cells which only secondarily form cartilage, while in a chondroma the cartilage grows in the same way as under normal conditions.

The mode of growth in cell tumours readily explains how it is that these tumours penetrate the surrounding structures instead of merely displacing them and how the cells find their way into the lymphatics and blood-vessels and so come to be distributed to distant organs.

The wasting and cachexia by which malignant tumours are often accompanied may probably be explained by the drain of nutritive material, especially carbohydrate, caused by the rapidly growing tumour.

The clinical features of malignant disease are very imperfectly dealt with in most books. The ordinary text-books of the result of previous tumour growth. 2. It is not always necessary to presuppose a rudiment consisting of the same kind of tissue as that of which the tumour is composed. It is evident, therefore, that the common factor in tumour formation is not to be found in the rudiment from which the tumour originates.

### GROWTH.

Having considered the rudiment from which the tumour springs we have next to direct our attention to the growth of the tumour from the rudiment. I shall postpone the consideration of the processes of cell division for the present. Tumours grow mainly, if not entirely, by centrifugal growth—that is, by proliferation of their own cells. Coats and others have supposed that, in the case of carcinoma, increase takes place by centripetal growth, that is, by the epithelium in the neighbourhood of the advancing tumour taking a share in the growth, but the evidence in favour of this view is not convincing Personally, I believe that the growth is centrifugal in all cases but that it is possible for the area of origin to extend by continuity. In some cases also it is possible that a malignant tumour may arise in multiple foci which subsequently fuse together. I agree with Ribbert that the examination of the growing margin of a tumour gives no information as to the structures from which it originated. Centrifugal growth may be either central or peripheral. If the growth is central the tumour will be definitely encapsuled; if peripheral growth occurs the capsule will be more or less indistinct and the tumour will be infiltrating. In order to consider the origin and mode of growth in more detail, it will be necessary to treat of the different classes separately.

*Organomata* —Many views have been held at different times as to the origin of the teratomata. Seeing that they occur most commonly in the ovary it is not unnatural to suppose that they originate in the germ-cells, either by the irregular development of a fertilised ovum or by a kind of parthenogenesis. This idea is unsatisfactory since, although the most complicated dermoids undoubtedly occur most frequently in the ovary, yet they are sometimes found in other parts of the body where germ-cells cannot be concerned. Nor is it sufficient to suppose that they arise in an abnormal inclusion of epiblast since the structures met with in these tumours are developed as much from the mesoblast as from the epiblast These tumours must be considered as errors of development just as other tumours may be regarded as errors of growth, and the increase in size is accompanied by a process of development, a fact which distinguishes them from other tumours. For instance, the bones met with in dermoids are not merely irregular masses of osseous tissue such as are found in other growths, but are definite bones with a distinct periosteum although, the development taking place without reference to the needs of the organism, the bones thus formed do not, as a rule, bear any resemblance to any individual bones. The difference between teratomata and malformations consists in the fact that in the latter the organs are found to be arranged in a more or less typical manner such as occurs, for instance, in a limb, a condition which we do not find in a teratoma As to the rudiment from which these tumours arise we do not know whether it consists of the structures usually present at the point of origin or of structures which have been included and are, in reality, derived from a distance

*Histiomata* —The growth of the tissue tumours takes place in exactly the same way as the growth of the normal tissues The tissues of the tumour during growth always preserve their proper characters; thus, the epithelium in an adenoma never loses its character as a tissue, it always forms a continuous membrane formed of cells in contact with each other lining tubes and spaces Tissue tumours grow, for the most part, by central growth Some fibromata, however, grow in part by peripheral growth and can therefore surround gland tubules, &c, so that they come to be imbedded in the tumour. The same is the case with some other tumours such as lipomata. The mode of growth in osteomata does not seem to have been determined; many growths called osteomata are in reality ossifying chondromata. The true osteoma such as is met with in the skull sometimes involves both tables and, from its macroscopic appearances, would seem to increase by centrifugal growth, that is, by proliferation of the osteocytes themselves This mode of growth would be in conformity with the growth of other tumours, but I have not had an opportunity of verifying it.

With regard to the epithelial histiomata the question arises: What part does the connective tissue play in the growth? Many authors regard the stroma as playing an equal part with the epithelium. I, however, look upon it as altogether secondary in importance to the epithelium. As epithelium is an avascular tissue it is entirely dependent on the surrounding connective tissue for its nutrition. If, therefore, the epithelium proliferate, there must be a concomitant proliferation of the neighbouring connective tissue. Epithelial histiomata arise by a proliferation of epithelium which gives rise to an increase of surface area. This increase can only be provided for by the occurrence of one of two events: either the proliferating area projects above the surrounding surface or it becomes invaginated into the subjacent tissue; in the former case the resulting tumour is a papilloma, in the latter it is an adenoma. In a papilloma the projecting area will necessarily carry with it a central core of fibrous tissue derived from the subjacent connective tissue of the part. Just as a papilloma may arise where there are normally no papillæ, so an adenoma may originate from a surface epithelium where there are no glands. I have seen a tumour of the bladder in which the epithelium, instead of projecting so as to form a papilloma as is usually the case, was invaginated into the subjacent tissue in the form of tubes lined with transitional epithelium without there being any penetration of the epithelial cells into the surrounding tissues, such as is the case in carcinoma; the growth was, moreover, clinically benign in character. Structurally the tumour corresponded exactly with an ordinary adenomatous polypus of the rectum. Similar growths have been described in the skin by Bland-Sutton[7] and others. In this position, as in the bladder and rectum, they form pedunculated tumours formed of tubes lined with epithelium. In all probability such tumours have occasionally been described as carcinomata, but they can be distinguished by the fact that there is no tendency for the individual epithelial cells to penetrate into the surrounding tissues. Epithelial histiomata often present a combination of papilloma and adenoma, especially in the bladder and rectum.

With a view to studying the origin and growth of these epithelial tumours I have applied the method of serial sections. By this method the errors of interpretation which arise from the examination of a single section are entirely eliminated and we can obtain a mental picture of the complete structure of the tumour. Unfortunately it is difficult to obtain tumours of sufficiently small size for this method to be applicable. From the examination of an adenoma of the rectum by this method I came to the conclusion[8] that it arose, not from the crypts of Lieberkühn but from the surface epithelium, the tubes of which it was composed being new formed by invagination from the surface A similar examination of the lobules of a large lobulated adenoma of the breast revealed the fact that al the epithelial tubes in the lobule were branches of a sing tube which entered the lobule from the main tumour. It is probable, therefore, that all the tubes in an adenoma of the breast are in direct continuity with each other, and that therefore they arise from a single epithelial rudiment.

*Cytomata* —The growth of the cell tumours differs from that of the tissue tumours in that the growing portions consist of cells more or less loosely held together but forming definite tissues. These cells readily penetrate the interstices of the surrounding tissues. Any tissues which may be present in cytomata are of not primary, formation.

Carcinomata arise from epithelium or endothelium. area of origin may be localised or may involve the whole an organ as in the rare cases of diffuse carcinosis met in the breast and kidney. The stroma is derived from the surrounding tissues and represents the reaction of the tissues against the invading epithelial cells. The growth in nomata is almost entirely peripheral, and takes place individual cells or small group of cells penetrating into the surrounding connective tissue spaces. This can be detected even in columnar-celled carcinomata, at the growing edge of which can be seen rows and groups of columnar invading the surrounding tissues, the tubes being formations The growth therefore differs entirely that of an adenoma in which the growth takes primarily in the form of tubes.

Sarcomata arise in any form of connective tissue and area of origin may be limited or may involve the whole the connective tissue of an organ, as is seen in the rare of diffuse sarcoma of the liver. Growth is both central and peripheral, and there is often a secondary formation of definite tissues such as fibrous tissue or cartilage. I have already considered the growth of the blastomata.

### TERMINATION.

Tumours in most cases continue to increase in size without attaining to any final termination. In some cases a limit is reached owing to a change in structure such as ossification or calcification. In other cases, again, a tumour after growing for a time may become stationary. In rare cases a tumour may decrease in size and ultimately disappear, and this without undergoing ulceration or necrosis. Sir William H. Bennett, in a clinical lecture at St. George's Hospital about three years ago,[9] gave examples occurring in his practice which show the possibility of malignant growths completely disappearing without any special treatment. In four cases verified microscopically as sarcoma the patients regained perfect health, the tumours disappearing completely. One of these was an abdominal spindle-celled sarcoma, two were melanotic sarcomata with disseminated growths, and the other was a sarcoma of the testis. In two cases of carcinoma in which the primary growth was removed and in which recurrence took place the recurrent growths subsequently became smaller and eventually almost completely disappeared. In one of these cases the primary growth was in the testis and in the other it was in the breast, and both were verified microscopically. Another case of carcinoma of the breast (not verified) was known to have remained stationary for 15 years. Another was a case of malignant disease of the pylorus with obstruction; this was not verified, but at the operation for gastrojejunostomy numerous secondary growths in the omentum and under the liver were seen and handled. In this case the patient recovered completely and was well five years after the operation, no growths being then discoverable. He also mentions a case of apparently malignant disease of the cervical glands too extensive for operation in which the patient recovered. Besides these remarkable cases—and they were only examples of many more which had come under the observation of Sir William Bennett—there have been recorded lately many cases of carcinoma of the breast which have improved after the operation of oöphorectomy in combination with thyroid feeding and other cases which have improved without special treatment. It is, therefore, a mistake to say that a tumour always continues to grow without limit; it may, under certain conditions which are imperfectly understood, become stationary or even diminish in size or disappear completely.

### PHYSIOLOGICAL CHARACTERS.

We have next to consider whether the cells and tissues of which a tumour is composed are capable of behaving physiologically like the cells and tissues of normal organs, or, in other words, are the cells and tissues of a tumour capable of performing any function? In considering this question we have to remember the fact that the cells of a tumour are in a state of more or less rapid proliferation and we should not, therefore, expect to find them very active in the performance of any function. Moreover, owing to the atypical arrangement which is characteristic of a tumour, there is no mechanism by which the performance of a function can be initiated, and, for the same reason, any function that may be performed is incapable of being utilised. The muscle-cells of a myoma, for instance, are probably capable of contraction, but, owing to the want of nervous connexion and the atypical arrangement, this power of contraction is not manifested and, if it did take place, it would serve no useful purpose. In spite of this there are several facts which show that the cells of a tumour are capable of functionating. The sebaceous glands of a dermoid secrete sebum, the cells of an adenoma or carcinoma of the intestine secrete mucin, adenomata of the thyroid contain colloid, and adenomata of the breast sometimes contain a milky fluid. Also the cells of a squamous-celled carcinoma undergo keratinisation, those of a carcinoma of the stomach form pepsin and rennin, and those of a carcinoma of the pancreas contain all the ferments proper to the pancreas, and this is true, at any rate in the case of the pancreas, of secondary, as well as of primary, growths (Waring).[10]

Perhaps the most remarkable physiological characteristic of tumour-cells is the property which they possess of storing enormous quantities of glycogen. In this respect, according to Brault,[11] they far exceed all the normal cells of the body and they can only be compared with the rapidly proliferating cells of the embryo. Those tumours which grow the most rapidly contain the greatest amount of glycogen, and from the study of the amount contained in a tumour the rate of growth can be judged. The cells of carcinomata and sarcomata are loaded with glycogen, while the surrounding tissues show a complete absence of it. The presence of this glycogen raises some interesting points for our consideration. Firstly, what is the meaning of this great store of carbohydrate material? Carbohydrate material is the great source of energy in the living organism; it is to the body what the fuel is to the steam engine. In the case of the embryo and in tumour formation energy is manifested by the multiplication of cells, and in order to supply this energy the cells store up carbohydrate in the form of glycogen. Secondly, what is the origin of the glycogen? Presumably it is formed in the same way as under normal conditions from the circulating glucose; if, however, the supply be deficient, it can be derived from the proteids of the body as in the severer forms of diabetes. Lastly, what becomes of the glycogen? Although there is such an enormous store of glycogen, yet, as far as I know, malignant disease is seldom or never accompanied by glycosuria. The glycogen is used up in the multiplication of cells because the central parts of a carcinoma, where proliferation has ceased, are completely free from it. It is probably directly oxidised and eliminated as carbon dioxide and water. This question of the presence of glycogen in tumours is well worth further study, especially by those who take a special interest in metabolic processes.

### PATHOLOGICAL CHANGES.

The pathological changes to which tumours are subject need not detain us since they are the same to which any normal tissue is liable. Tumours are liable to the various retrogressive processes, especially to mucoid and fatty changes and calcification, to necrosis, to inflammation and repair, and to the formation of new tumours.

### CLINICAL CHARACTERS.

It will be noticed that in the classification which I have given the histiomata and cytomata correspond respectively to the simple and malignant tumours of a clinical classification. Most authors state that tumours, usually simple, may occasionally take on malignant characters, and this is especially supposed to be the case with chondromata. This idea is based chiefly on a case reported by Paget of a chondroma of the testis which gave rise to metastatic growths in the lungs and elsewhere. This case, however, was re-investigated by Kanthack and Pigg,[12] who found that it was not a pure chondroma, but that it contained carcinomatous elements, and in the same way it will, I think, be found that whenever a tumour that is apparently a tissue tumour displays malignant properties it is in reality a cell tumour.

In my opinion the difference between simple and malignant tumours is to be found in the manner in which they grow. The growing area of a cell tumour consists of cells, either separate or in small groups, not forming any definite tissue, any formed tissues that may be present in the tumour being of secondary formation. The tissues in a tissue tumour, on the other hand, are of primary formation. For example, the growing area of a columnar-celled carcinoma consists of columnar cells in rows or groups which only secondarily give rise to epithelial tubes, whereas in an adenoma the growing area consists of epithelial tubes similar to those in the older parts of the tumour. Similarly in a chondro-sarcoma the growing area consists of collections of cells which only secondarily form cartilage, while in a chondroma the cartilage grows in the same way as under normal conditions.

The mode of growth in cell tumours readily explains how it is that these tumours penetrate the surrounding structures instead of merely displacing them and how the cells find their way into the lymphatics and blood-vessels and so come to be distributed to distant organs.

The wasting and cachexia by which malignant tumours are often accompanied may probably be explained by the drain of nutritive material, especially carbohydrate, caused by the rapidly growing tumour.

The clinical features of malignant disease are very imperfectly dealt with in most books. The ordinary text-books of the result of previous tumour growth. 2. It is not always necessary to presuppose a rudiment consisting of the same kind of tissue as that of which the tumour is composed. It is evident, therefore, that the common factor in tumour formation is not to be found in the rudiment from which the tumour originates.

### GROWTH.

Having considered the rudiment from which the tumour springs we have next to direct our attention to the growth of the tumour from the rudiment. I shall postpone the consideration of the processes of cell division for the present. Tumours grow mainly, if not entirely, by centrifugal growth—that is, by proliferation of their own cells. Coats and others have supposed that, in the case of carcinoma, increase takes place by centripetal growth, that is, by the epithelium in the neighbourhood of the advancing tumour taking a share in the growth, but the evidence in favour of this view is not convincing. Personally, I believe that the growth is centrifugal in all cases but that it is possible for the area of origin to extend by continuity. In some cases also it is possible that a malignant tumour may arise in multiple foci which subsequently fuse together. I agree with Ribbert that the examination of the growing margin of a tumour gives no information as to the structures from which it originated. Centrifugal growth may be either central or peripheral. If the growth is central the tumour will be definitely encapsuled; if peripheral growth occurs the capsule will be more or less indistinct and the tumour will be infiltrating. In order to consider the origin and mode of growth in more detail, it will be necessary to treat of the different classes separately.

*Organomata.*—Many views have been held at different times as to the origin of the teratomata. Seeing that they occur most commonly in the ovary it is not unnatural to suppose that they originate in the germ-cells, either by the irregular development of a fertilised ovum or by a kind of parthenogenesis. This idea is unsatisfactory since, although the most complicated dermoids undoubtedly occur most frequently in the ovary, yet they are sometimes found in other parts of the body where germ-cells cannot be concerned. Nor is it sufficient to suppose that they arise in an abnormal inclusion of epiblast since the structures met with in these tumours are developed as much from the mesoblast as from the epiblast. These tumours must be considered as errors of development just as other tumours may be regarded as errors of growth, and the increase in size is accompanied by a process of development, a fact which distinguishes them from other tumours. For instance, the bones met with in dermoids are not merely irregular masses of osseous tissue such as are found in other growths, but are definite bones with a distinct periosteum although, the development taking place without reference to the needs of the organism, the bones thus formed do not, as a rule, bear any resemblance to any individual bones. The difference between teratomata and malformations consists in the fact that in the latter the organs are found to be arranged in a more or less typical manner such as occurs, for instance, in a limb, a condition which we do not find in a teratoma. As to the rudiment from which these tumours arise we do not know whether it consists of the structures usually present at the point of origin or of structures which have been included and are, in reality, derived from a distance.

*Histiomata.*—The growth of the tissue tumours takes place in exactly the same way as the growth of the normal tissues. The tissues of the tumour during growth always preserve their proper characters; thus, the epithelium in an adenoma never loses its character as a tissue, it always forms a continuous membrane formed of cells in contact with each other lining tubes and spaces. Tissue tumours grow, for the most part, by central growth. Some fibromata, however, grow in part by peripheral growth and can therefore surround gland tubules, &c., so that they come to be imbedded in the tumour. The same is the case with some other tumours such as lipomata. The mode of growth in osteomata does not seem to have been determined; many growths called osteomata are in reality ossifying chondromata. The true osteoma such as is met with in the skull sometimes involves both tables and, from its macroscopic appearances, would seem to increase by centrifugal growth, that is, by proliferation of the osteocytes themselves. This mode of growth would be in conformity with the growth of other tumours, but I have not had an opportunity of verifying it.

With regard to the epithelial histiomata the question arises: What part does the connective tissue play in the growth? Many authors regard the stroma as playing an equal part with the epithelium. I, however, look upon it as altogether secondary in importance to the epithelium. As epithelium is an avascular tissue it is entirely dependent on the surrounding connective tissue for its nutrition. If, therefore, the epithelium proliferate, there must be a concomitant proliferation of the neighbouring connective tissue. Epithelial histiomata arise by a proliferation of epithelium which gives rise to an increase of surface area. This increase can only be provided for by the occurrence of one of two events: either the proliferating area projects above the surrounding surface or it becomes invaginated into the subjacent tissue; in the former case the resulting tumour is a papilloma, in the latter it is an adenoma. In a papilloma the projecting area will necessarily carry with it a central core of fibrous tissue derived from the subjacent connective tissue of the part. Just as a papilloma may arise where there are normally no papillæ, so an adenoma may originate from a surface epithelium where there are no glands. I have seen a tumour of the bladder in which the epithelium, instead of projecting so as to form a papilloma as is usually the case, was invaginated into the subjacent tissue in the form of tubes lined with transitional epithelium without there being any penetration of the epithelial cells into the surrounding tissues, such as is the case in carcinoma; the growth was, moreover, clinically benign in character. Structurally the tumour corresponded exactly with an ordinary adenomatous polypus of the rectum. Similar growths have been described in the skin by Bland-Sutton[7] and others. In this position, as in the bladder and rectum, they form pedunculated tumours formed of tubes lined with epithelium. In all probability such tumours have occasionally been described as carcinomata, but they can be distinguished by the fact that there is no tendency for the individual epithelial cells to penetrate into the surrounding tissues. Epithelial histiomata often present a combination of papilloma and adenoma, especially in the bladder and rectum.

With a view to studying the origin and growth of these epithelial tumours I have applied the method of serial sections. By this method the errors of interpretation which arise from the examination of a single section are entirely eliminated and we can obtain a mental picture of the complete structure of the tumour. Unfortunately it is difficult to obtain tumours of sufficiently small size for this method to be applicable. From the examination of an adenoma of the rectum by this method I came to the conclusion[8] that it arose, not from the crypts of Lieberkühn but from the surface epithelium, the tubes of which it was composed being new formed by invagination from the surface. A similar examination of the lobules of a large lobulated adenoma of the breast revealed the fact that all the epithelial tubes in the lobule were branches of a single tube which entered the lobule from the main tumour. It is probable, therefore, that all the tubes in an adenoma of the breast are in direct continuity with each other, and that therefore they arise from a single epithelial rudiment.

*Cytomata.*—The growth of the cell tumours differs from that of the tissue tumours in that the growing portions consist of cells more or less loosely held together but not forming definite tissues. These cells readily penetrate into the interstices of the surrounding tissues. Any formed tissues which may be present in cytomata are of secondary, not primary, formation.

Carcinomata arise from epithelium or endothelium. The area of origin may be localised or may involve the whole of an organ as in the rare cases of diffuse carcinosis met with in the breast and kidney. The stroma is derived from the surrounding tissues and represents the reaction of the tissues against the invading epithelial cells. The growth in carcinomata is almost entirely peripheral, and takes place by individual cells or small group of cells penetrating into the surrounding connective tissue spaces. This can be detected even in columnar-celled carcinomata, at the growing edge of which can be seen rows and groups of columnar cells invading the surrounding tissues, the tubes being secondary formations. The growth therefore differs entirely from that of an adenoma in which the growth takes place primarily in the form of tubes.

Sarcomata arise in any form of connective tissue and the area of origin may be limited or may involve the whole of the connective tissue of an organ, as is seen in the rare cases of a sarcoma arising at the site of a fracture in a bone. These extrinsic factors, which are known by the general term *irritants*, are also the exciters of inflammatory processes, but there is this difference between the two cases. When inflammation follows the action of an irritant the amount of inflammation depends on the amount of irritation and on removing the irritant the inflammatory process ceases and the injury is made good; in the case of a tumour following the action of an irritant, on the other hand, the action of the irritant may be momentary while the growth of the tumour is prolonged and the removal of the irritant does not cause the cessation of the tumour growth.

---

[7] Transactions of the Pathological Society of London, 1892.

[8] Journal of Pathology and Bacteriology, vol. vii.

These extrinsic factors, therefore, cannot be the essential causal factors of tumour formation and can only be remote factors which act through the medium of intermediate intrinsic factors. We must, however, consider the possibility of the existence of a special extrinsic factor, such as an animal or vegetable parasite. The theory of parasitic causation of tumour formation has gained a large amount of acceptance at the present time and, indeed, almost all those who are working at the subject are approaching it from this point of view. This theory is only supposed to apply to those tumours which are malignant, but it is equally necessary to explain the formation of simple tumours if an extrinsic factor is thought to be essential at all, because the continuous and increasing growth of the tumour demands a continuous and increasing causal factor. I myself have not engaged in the search for a parasite although I have seen the bodies claimed to be of that nature. I have, however, studied minutely the histology and general pathology of tumours with a view to determining whether or not tumour formation can be explained by this theory and I have come to the conclusion that the essential causal factor cannot be found in any extrinsic irritant, whether parasitic or not. On account of the importance of this theory it is necessary to examine it closely and carefully to consider the arguments on both sides. In the following remarks I shall, for the sake of simplicity, use the term carcinoma, but the arguments will, as a rule, equally apply to sarcoma.

### Parasitic Theory.

In discussing this theory, I shall first consider the basis on which it is founded, afterwards I shall consider in detail various objections which can be brought against it. The theory is based :—

1. *On the apparent resemblance of carcinoma to infective diseases such as tuberculosis.*—Carcinoma, at first sight, closely resembles tuberculosis in many respects. Both have a local origin and give rise to secondary deposits, first in the regional lymphatic glands, and later in the various organs of the body. When, however, we come to study the histology of the lesions in the two cases, the resemblance at once disappears. We find that the tuberculous nodule is made up of cells which are derived partly from cells which have exuded from the blood-vessels, and partly from the tissues of the part in which the bacillus has settled. A carcinomatous nodule, on the other hand, is composed of cells which are derived in secondary growths not from the part in which the growth is situated, but from the primary tumour, wherever this may be placed. We can, indeed, compare the epithelial cells of the carcinomatous nodule with the bacilli in a tubercle, and if we do this the analogy between the two diseases is complete, the stroma of the carcinoma corresponding to the histological tubercle, while the epithelial cells correspond with the bacilli in the tubercle. If, however, the comparison is made in this way the argument in favour of the parasitic origin of carcinoma from the analogy with tuberculosis completely fails, because, if we grant that the tubercle bacilli are capable of spontaneous proliferation, we cannot argue that their analogues, the epithelial cells of a carcinoma, can only proliferate under the influence of a parasite.

2. *On the inoculability of malignant growths.*—A few cases are on record in which a patient afflicted with carcinoma has apparently infected another person with the disease; these cases are, however, extremely rare and would seem to be no more than coincidences. If tumours were due to parasites we should expect the infectivity to be much more marked. Growths are sometimes met with on the genital organs of bulldogs; they have been especially described by Washbourn and Bellingham Smith[15] under the name of infective sarcomata. These growths are highly contagious but show only a slight degree of malignancy; they are slow of growth and rarely give rise to metastasis and they cannot be transferred to any animals except dogs. Microscopically they closely resemble round-celled sarcomata. In two cases which I have had the opportunity of examining the growths had been present for 12 months and yet there was very little infiltration of the surrounding parts. Both were situated in the vagina and in one case there was a secondary growth in one of the mammary glands, yet, notwithstanding this, a complete cure took place after the removal of the affected part of the vagina and the secondary growth. As, therefore, these growths differ so largely from sarcomata as we meet them in man, we must be careful how we use them as an argument in favour of the parasitic theory. The fact that a tumour is inoculable does not necessarily imply that it is due to a parasite. The infective agent may very well be the epithelial cells themselves, since it must not be forgotten that they are living units. In skin-grafting we see that epithelial cells can be transplanted and, if this is true of normal cells, it is probably true also of the cells of a carcinoma. Malignant tumours have been successfully transferred from one animal to another but only if the two animals are of the same species.

3. *On the analogy with the lesions produced in the rabbit's liver and elsewhere by the coccidium oviforme.*—In coccidiosis of the liver we find numerous small cavities which are filled with the coccidia in various stages of development. On examining these spaces we find that they are lined by columnar epithelium and are evidently local dilatations of the bile-ducts. The younger forms of the parasite are found within the epithelial cells while the older are lying free in the cavity. This has been regarded as an example of true tumour formation caused by a parasite. I have not myself examined critically many of these cases, but from what I have seen I am more inclined to look upon them as a kind of retention cyst caused by the accumulation of the parasites in much the same way as bronchiectasis may be due to the accumulation of the bronchial secretion. The proliferation of the epithelium would in that case be of the same nature as that found in catarrhal inflammation. Occasionally the parasites are found in a cavity in the connective tissue and in that case the wall of the cavity consists of fibrous tissue without any epithelial lining, as would be the case with any other chronic irritant. In any case we do not in coccidiosis find the essential lesion of carcinoma—namely, penetration of the connective tissue by the epithelial cells,—so that if any conclusion is to be drawn from the supposed analogy it is that non-malignant tumours are caused by parasites.

4. *On the topographical distribution of carcinoma.*—Carcinoma may in a sense be called a disease of civilisation—that is, it is more frequent among civilised nations than among savages and it is more common among domesticated than among wild animals. It is said to be more frequent in valleys the rivers of which are liable to floods. These are conditions which affect the general health and it does not seem necessary to assume a parasite in explanation. In some places there are said to be certain houses the inmates of which are more liable to cancer than are those of other houses, but we require more information on this point before we can draw any conclusions from it.

The above four facts are the bases on which is founded the general idea that malignant growths are due to parasites. There remains to be considered the question whether carcinoma is due to certain bodies described as parasites which are found in the tumour cells. From time to time during the last 11 years certain structures which are found within and between the cells of carcinomata have been described by numerous observers as parasites. There is, however, no agreement among the different observers as to the nature of these bodies nor as to which of the various cell inclusions are and which are not parasitic in nature. Two of the best papers which have been published of late years on this subject are those by Plimmer[16] and Gaylord.[17] Plimmer describes the parasite as a round body varying in size from 0·004 to 0·04 millimetre or more in diameter. In the centre is a minute body which he calls a nucleus, although, as he says, it probably does not correspond with the nucleus of an ordinary cell. Round the nucleus is a layer of homogeneous protoplasm which is bounded by a definite capsule. According to Plimmer, the nucleus of the parasite differs from the nucleus of a cell in its staining properties by refusing basic stains such as hæmatoxylin and medicine—even Allbutt's System of Medicine—are silent on the medical aspects of carcinoma and sarcoma and little is to be gathered from other sources. There seems to be no full account of the temperature and urine, and the blood has not received the attention that it deserves. We require much more information as to these points, especially with regard to the excretion of nitrogen.

## LECTURE II.

*Delivered on Feb. 12th.*

MR. PRESIDENT AND GENTLEMEN,—In this lecture I propose to consider certain theories which have been advanced to explain the causation of tumours, but it will first be necessary to draw your attention to the minute structure of the cell and to the changes which it undergoes during the process of cell division.

### CELL STRUCTURE AND CELL DIVISION.

In the normal cell at rest the following constituents can be recognised.[13] 1. The *cytoplasm* or protoplasm of the cell body. 2. The *nucleus*, which consists of the following parts: (*a*) the *nuclear membrane*, which gives to the nucleus its sharp contour; (*b*) the *nuclear reticulum*, which consists partly of chromatin, which is the most important constituent and which gives to the nucleus its intense staining properties, and partly of linin, which resembles the cytoplasm in staining reactions; (*c*) the *nucleoli*, of which there are two kinds, the *plasmosomes* or true nucleoli, which stain like the cytoplasm, and the *karyosomes*, which stain like the chromatic substance; and (*d*) the *karyolymph*, which occupies the meshes of the nuclear reticulum. 3. Lastly, there is the *centrosome*, which is usually situated in the cytoplasm, but which is occasionally found in the nucleus. The centrosome is a permanent constituent of some cells, but it has not been shown to be so in all. It appears as a minute body staining with the nuclear dyes and is surrounded by a spherical body known as the *centrosphere* or attraction sphere. From the centrosome there often radiate achromatic fibres forming the *aster*. The functions of the centrosome are not yet fully known, but there are reasons for regarding it as the dynamic centre of the cell—that is, the centre which regulates the movements of the cell. In some cells the centrosome has been found to have intimate relations with the cilia; this is especially the case in the spermatozoon in which the centrosome is found in the middle piece at the attachment of the tail. In the leucocyte the centrosome and aster are permanent and are supposed by some to influence the amœboid movements. In epithelial cells the centrosome is usually found towards the free border of the cell. The chromatin of the nucleus at rest is arranged in the form of a network. Now, the first indication of division of the cell by mitosis is found in the centrosome which divides. This division sometimes takes place immediately after the preceding division, so that the centrosome in the resting cell often appears double. The two halves then separate and, at the same time, there appears a structure composed of achromatic fibres known as the *amphiaster*, which consists of an aster at each end with its centre at the centrosome and the intervening *achromatic spindle* uniting the two centrosomes. At the same time that these changes are taking place in the centrosome the nucleus undergoes alterations; the chromatin becomes arranged in the form of a skein or *spireme*, which then splits into a certain number of segments called *chromosomes*, which are themselves composed of minute granules called *chromomeres*. The chromomeres next undergo division in such a way that each chromosome comes to consist of two parallel rows of chromomeres. The nuclear membrane has by this time disappeared and the chromosomes are drawn into the axis of the achromatic spindle, to the fibres of which they become attached. The two halves of the chromosomes, then, under the influence of the achromatic fibres, become separated and pass towards the centrosomes and finally rearrange themselves so as to form the nuclei of the daughter cells. The cell body begins to divide as the chromosomes separate, apparently also under the influence of the achromatic substance. We thus see that, while the division of the chromosomes is spontaneous, their separation is due to the action of the centrosomes and the amphiaster and that, in consequence, the centrosome should be considered as the prime agent in the division of the cell.

The centrosome and its associated achromatic substance or *archoplasm* have been strangely neglected by pathologists, although they form such an important part of the cell. Under normal conditions the result of mitosis is that each daughter cell contains exactly the same number of chromosomes as the mother cell, this number being fixed for each species of animal. In animals multiplying by sexual reproduction this number is always even, and in man it is said to be 16. I have been able to verify this number in the case of a few carcinoma cells which I have come across in which it has been possible to enumerate the distinct chromosomes.

In malignant growths and in some other conditions accompanied by rapid proliferation we often find a deviation from the typical form of mitosis; thus we find *asymmetrical mitosis*, in which the daughter cells contain an unequal number of chromosomes, and *multipolar mitosis*, in which the cell divides simultaneously into more than two daughter cells. Multipolar mitosis arises from the division of the centrosome into more than two parts; each part is associated with a cone of achromatic fibres which passes to the chromosomes. I have not been able to determine the number of chromosomes in the daughter nuclei in these cases. In most cases of quadripolar mitosis which I have seen the daughter nuclei were not in the same plane but were at points corresponding to the angles of a regular tetrahedron.

*Amitosis*, or direct division, is often met with in malignant tumours and especially in those which are undergoing degeneration. In this mode of division the nucleus becomes divided in two by a septum; the two halves then separate and this is followed by division of the cytoplasm. Frequently, however, the cell body fails to divide and thus arise cells with two or more nuclei. Another method of amitosis is described by Brault,[14] and from my own observations I can confirm his description. In this method the nucleus becomes drawn out into two or more parts, each part becoming the nucleus of a daughter cell. In other cases the nucleus may give off buds which form daughter nuclei. Occasionally the nucleus becomes split up into a number of chromatin particles of varying size which become scattered in the cytoplasm. That is known as fragmentation or *karyorrhexis*.

*Endogenous formation* of cells used to be thought a common event in carcinoma; lately, however, doubts have been thrown on its existence, chiefly by those who uphold the parasitic theory. Personally I have no doubt that this process does occur and I should describe the method as follows. A portion of the nucleus becomes separated by fragmentation or budding, it then gathers round it some of the neighbouring cytoplasm which becomes separated from the rest of the cell body, and thus forms a daughter cell which gradually increases in size until it becomes a fully formed cell lying in a vacuole in the mother cell. In other cases the daughter cell is the result of an amitotic division in which one of the resulting cells lies within the other instead of separating from it as is usually the case. In this connexion it must be remembered that the chromomeres, of which the nuclear chromatin is composed, are, to a certain extent, living units capable of division and growth, so that it may be possible for a minute portion of the nucleus to grow so as to form the nucleus of a new cell. These included cells are of common occurrence in some carcinomata and sarcomata, and it is not uncommon to see a granddaughter cell within the daughter cell. I have proved by means of serial sections that these cells are really inclosed and not merely invaginated, and it is difficult to conceive how they come to be so inclosed unless they are formed *in situ*.

### EXTRINSIC CAUSES.

Causal factors may be divided into those which are of extrinsic and those which are of intrinsic origin. When we speak of a disease as a whole the term *extrinsic* implies that the factor is derived from outside the body; when, however, a disease is considered in its relation to any particular organ the term implies that the causal factor is derived from outside that organ, but not necessarily from outside the body. Extrinsic factors undoubtedly play an important part in the causation of tumour formation. Tumours may arise as a result of chronic irritation such as that produced by constant friction or by the presence of a chronic ulcer; they have also been ascribed to a blow or sudden injury as in the case which contain the inclusion do not divide, but, as a rule, begin to show degenerative changes similar to those in phagocytic cells in other diseases when the cells cannot conquer. These degenerative changes would, however, seem to be very slight in amount.

[13] Wilson: The Cell in Development and Inheritance.

[14] Manuel d'Hist [illegible] Pathologique

As regards the relation between the supposed parasite and the cell, we have to consider how the parasite, in the case of intracellular parasites, enters the cell. Is the entrance active on the part of the parasite or passive as in phagocytosis? or does the parasite fulfil its whole cycle within the cell? The last supposition is impossible, for, since the containing cell does not divide, the parasite would not have any opportunity of continuing its existence when the cell had degenerated. If the entrance is an active process on the part of the parasite it is difficult to understand how a parasite which causes destruction of the cell into which it enters can cause active proliferation of the surrounding cells. If, on the other hand, it is a phagocytic action on the part of the cell, how is it that the youngest forms of parasite which are described are either within or close to the nucleus? The abnormal increase in the phagocytic properties of the epithelial cells is left wholly unexplained. Mr. Plimmer tells me that there is not sufficient evidence to show whether the entrance of the parasite into the cell is active or passive.

An example of true defensive reaction is seen in catarrhal inflammation. In this the affected epithelial cells degenerate and are cast off, those that are left proliferating to take their place. In carcinoma, however, the affected cells are not cast off, but penetrate into the deeper tissues; it is, therefore, the exact opposite of a defensive reaction. If, therefore, carcinoma be due to a parasite, we have the curious phenomenon of the organism not attempting in any way to defend itself against an injurious parasite. This would be a unique occurrence in the processes of disease. It might be suggested that the parasites spread into the connective tissue and are followed by the proliferating epithelial cells. This is highly improbable and implies a mechanism of defence which is entirely unknown and yet there would seem to be no reason why the ordinary means of defence should not be available. Another objection to the theory is the fact that we are not told whether each species of carcinoma and sarcoma has its own parasite, or whether they are all due to the same parasite. The different species of carcinoma are usually so distinct that it is difficult to suppose that they are due to the same parasite. If this were the case we should expect to find the metastatic growths differing according to the kind of epithelium in which they occur. For instance, in the case of a squamous-celled carcinoma with secondary deposits in the liver we should expect to find the latter composed of spheroidal cells derived, by the action of the parasite, from the liver cells, but this is a state of things that we do not meet with. Moreover, if sarcoma and carcinoma are, as Plimmer and Gaylord suggest, due to the same parasite, how is it that we do not meet with a primary carcinoma giving rise to secondary sarcomatous deposits? If, on the other hand, each species has its own parasite, how are we to account for those tumours which show intermediate forms between the better marked species? In columnar-celled carcinoma of the uterus we occasionally find areas of squamous cells lying among and evidently formed from the columnar cells. There are also the highly complicated compound sarcomata which it would be impossible to explain on the supposition that each kind of sarcoma has its own parasite. Again, if each kind of tumour has its own parasite, we must suppose a series of parasites each of which are only capable of acting upon one kind of cell. It would therefore be necessary to suppose different carcinoma parasites for each gland in the body and we should also have to suppose a different series of parasites for each species of animal. Either of these suppositions, therefore, lands us in inextricable difficulties.

The parasitic theory, *then*, will *not explain* the production and growth of the primary tumour, nor will it explain the different species and the manner in which they breed true. Will it explain metastasis? Here, at all events, this theory ought to be capable of affording an explanation, since it is this feature which has afforded the chief ground on which the theory is based. In reality, however, instead of assisting the explanation of this feature, it increases the difficulty.

A metastatic growth cannot be due simply to the presence of a parasite for, if it were, we could not have a metastatic carcinoma in a position devoid of epithelium. We must therefore conclude that, besides the parasite, at least one epithelial cell must be transferred from the primary growth to form the mother cell of the secondary deposit, but this cell cannot be the cell in which the parasite is lodged, since the parasite-containing cells, at least in the case of the described parasites, do not proliferate but undergo degeneration. Therefore we must imagine a parasite and a cell independently conveyed to the site of the metastatic growth. Again, the adoption of this theory will not explain the situation of the primary growth. It will not explain, for instance, the frequency of malignant disease in the female organs of generation or the rarity of it in situations in which we should expect it to be frequent, such as the lungs and small intestine. Nor does it explain why the acini of the breast are more frequently affected than the ducts. In the case of sarcoma it is even more unsatisfactory, since, except in the rare cases of sarcoma starting in a wound, we must suppose the parasites conveyed to the seat of the tumour by the blood, and if this were the case we should expect multiple primary growths to be common

Carcinoma differs markedly from parasitic diseases in the almost absolute natural immunity possessed by children. To no parasitic disease is there such an absolute natural immunity at any particular period of life as there is to carcinoma during the first two decades. Brault[22] finds an objection to this theory in the fact that in malignant tumours the cells contain large quantities of glycogen, while in the cells resulting from parasitic irritation there is none. In the coccidium nodules in a rabbit's liver the glycogen is situated, not in the epithelial cells, but in the parasites themselves. Another important objection is the fact that it cannot by any possibility explain the origin of congenital sarcomata, and especially those tumours which I have called blastomata. In the case of tumours associated with the presence of bilharzia ova we find that the ova are not the immediate cause of the tumour, but are only remote causes since they are found, not in the tumour itself, but in the neighbourhood. Finally, there is the important fact that all the phenomena of malignant and other tumours can be explained on other grounds—namely, on the view that the cells take on an independent mode of growth and behave as parasites themselves.

We thus see that while the grounds on which this theory is based are inadequate the theory itself will not explain any of the phenomena of malignant disease. We are therefore justified in saying that malignant growths are not to be explained on the assumption of special extrinsic causal factors. It is equally impossible to explain the occurrence of tissue tumours on the parasitic theory, although, as I have shown, if these tumours are due to extrinsic causal factors, these factors must necessarily be of the nature of parasites. But it will be said that extrinsic factors are not necessary to explain simple tumours; to this I answer that there is no justification for separating the tissue tumours from the cell tumours so as to say that, while the one are due to intrinsic factors alone, extrinsic factors are necessary to explain the others. The common factor, therefore, in tumour formation is not to be found in the extrinsic causal agents.

### INTRINSIC CAUSES.

We have next to consider the intrinsic factors concerned in the causation of tumours, that is, the factors which arise within the organism at the seat of origin of the tumour. Thiersch, in 1865, called attention to the fact that in old age the connective tissue of the body undergoes atrophy and in consequence becomes unable to withstand the ingrowth of the more active cutaneous epithelium, and to this fact he attributed the origin of cutaneous carcinoma. Cohnheim, who attempted to find the common factor in tumour formation in the rudiment from which the tumour springs, made use of this observation of Thiersch to illustrate his views on the nature of malignancy. According to this author malignancy depends, not on any structural peculiarity of the tumour itself, but on a diminution of the physiological resistance of the surrounding tissues which enables the tumour cells to penetrate into and to destroy them. This diminution of the physiological resistance might be caused by an antecedent inflammatory condition or by the atrophy consequent on old age, or it might be inherited. Woodhead,[23] in his Morton Lecture delivered before this College in 1892,
